I do not own and have no experience with the Pixel antenna.

I do own a Wellbrook AL330S. I had trouble with it a few years ago when it was about 1 year old. Andy promptly sent a replacement loop after I contacted him and provided the results from my diagnostic procedures.

My Wellbrook support experience was very positive and I will provide kudos where they are due.

Tom

I can agree with this, support from Wellbrook is top notch and you won't get ripped of if you need spares. The new design of replacement head amp looks very easy to fit.

If you want to start with the classic ALA1530 you can always upgrade to an Imperium later as the extra amplification resides in the power inserter box.

I have 3 Wellbrooks, two ALA1530 types and one Imperium, they are all very good. My oldest one was bought in the late 90's and I upgraded it last year to include the latest amplifier design.

At my previous QTH, I had all sorts of wire antennas. My thirty odd year mainstay was a long wire of 145ft, but it's siblings over the years included dipoles, TTFD, AD Sloper, etc - always with my QRM source out in front of my house - the three HV phases feeding my subdivision 'bent' at an apex in front of my house, causing stress cracks in their insulators - and in three decades, Alabama Power wouldn't replace them, although they spent a fortune over the years with truck crews as frequent visitors, mainly tightening connections. My aperiodic QRM made DXing very spotty. My LW was lost due to it's house end support, a 70ft pine, loosing much of it's top half. Similar fates befell my other wire antennas - I quit listening for a while. One day, I elected to spend some money - a grand - and ordered a Palstar R30A and a Pixel Pro-1a. The latter proved to be much more useful.

In comparison - and from logs, where the background noise level on my R390A would run 40-45db on it's carrier meter while the NRD-525 ran S6-S8 and the R8 ran S7 - all daytime 'clear' around 6 MHz. I mounted the Pro-1a 12ft behind my house at ~8ft above the ground on my deck's apron via a five foot mast in an eave mount. I adjusted it for minimal noise - no more R390A, but the NRD-525 & R8 were within a half S unit of the logged signals of several stable stations - WWV (2.5, 5, 10, & 15 MHz), CFRX 6.07, ABC 9.58MHz, etc - and that's plus or minus half an S unit. A MW local was 'in the mud' - nulled! I was happy until 1/12 when a tornado twisted my loop around it's mount - and knocked out the power in the subdivision as it lay waste to my neighbors. APC set new poles and wires - but must have found some more 'vintage' insulators - I then needed to null in two directions. Skip ahead to 7/13 - I moved to a garden home with a tall walk-up attic. I bought a tripod mast base and loaded my loop, still on it's 5ft mast, into my Jeep and unloaded it at the new house, immediately carrying it and the tripod up into the end-of-July near 100F outside temp attic. Ten minutes later, having set it in the tripod in the center, some ten feet from the HVAC, and finding an unused RG6 feed to my office to repurpose as the loop's feed, I went down to my office and hooked up that end. Wow - underground utilities are great - nothing to null, save some 6.2 & 9.3 MHz digital hash DFed to my fiber optic modem in the yard. S2-S3 daytime, I can live with. Other digital noise from my 25" LCD PC monitor evaporated when I replaced the crimped connector, BNC to UHF, with one I soldered together - with Belden cable. In fairness, QS RG6 with adapters worked as well. In any case, signals are nearly as strong - within a half S-unit - of what they were. Noise is all but not existent (Radio Australia, this late - 1345 UTC, is 10db/S9, with 10 MHz WWV S9 - on my R30A 6kHz BW. Background noise at 9.700 MHz is S1-S2 at most.), thanks to the buried power lines no doubt.

Is the Pixel Pro-1a the answer to everyone's needs? No way - and no wonder your loop has a stronger signal, Rick - it has ten times the pickup area! Did you make sure the loops were parallel to each other and several wavelengths apart? Oddly, the amplified magnetic field loop seems to work best 6-10 ft off of ground - and away from metal (towers, guys, etc). Sure, the amplifier introduces some noise - but, in my experience, not much at all. With my home's 'Home Owner's Association' and it's no outside antenna edict, save a satellite TV dish, it is my 'answer'. I am sure the Wellbrook would do as well... but I was in a 'national pride' mood - both the Pixel and the Palstar are made in the USA.

The two loops in question use differing topologies i.e. Mobius verses a balanced loop.
It would be interesting to know what was the basis of using the Mobius loop; other than it sounds impressive being the work of Dr. Carl Baum while working for the USAF, given that it has yet to prove its self to offer any improvement over conventional screened or balance wideband loops.
Maybe someone from Pixel could shed some light on this.

From: everettsharp@...
Topic: 10692 Message: 10692

I have four, very unique and one of a kind, tuned air core loop antennas for sale, each of the loops are hexagonal shaped and are works of art. They are made from quarter sawn Red Oak and wound with 330/46 Litz wire. They are each mounted on Lazy Susan's. They have high Q Russian variable capacitors with a 3:1 reduction drive and have coupling loops that are connected to a matching transformer to give a 50 ohm output. Two of the loops are 1 meter in size, one is for MW covering 470 to 1745 KHz, the other 1 meter loop in for LW covering from 150 to 630 KHz.

One of the loops is a dual band design, covering 480 to 1960 KHz and the second band covers 1870 to 4480 KHz. The smallest loop is the equivalent of a 2' box loop, but is hexagonal shaped and covers the MW band.

I will not ship any of these loop antennas, as they could be easily damaged in shipment. I live in Tuscaloosa, AL, so any buyer would have to pick them up at my home. If anyone has interest in any of these antennas and needs more information and pictures please email me off list, everettsharp (at) A O L.

Hello sir, I am K9TEN and am working in Kuwait as a contractor for over the past 3 years. I live in Harvest, Alabama and will be home for good in November 2014. I am very interested in maybe buying one of your loops and when I get home would be glad to drive to pick one up. Maybe you have some pictures and additional information on them. I am looking mostly for any type of loop for the three bands that I have the most trouble with 40, 75, and 160 meters. I have been hit 2ea times by tornado's and have no tall trees/towers left for antennas for these bands. Thank you and have a great day. 73's Craig K9TEN

Thanks again for the help. I decided to buy a Wellbrook. All I can say is wow! I hooked it up temporarily in my garage, leaning up against a wall and it completely blows away the pixel. My pixel never worked this good when it was new. I can't wait to get it up on my mast to really hear it work.

Chris

Hi Chris,

User results speak volumes, yet if you read Pixels website, their loop is the best!...of course what else would you expect to read on the manufactures website.
The real world experiences from actual users helps others in making decisions prior to any purchasing.

When you get the time, may I request if you will to please post:
1). Which Wellbrook model you purchased?
2). What bands-frequency's you mainly use the loop for?
3). How it's mounted...How high?...Is it on a rotator?
4). If you have a transmitting antenna, how close do you install your loops in relation to the transmit antenna?...How much power you transmit with? if you do transmit, and if so do you disconnect or short your transmit antenna when receiving to prevent any potential interaction?

Sorry for all the questions...your replies will help me in my research in preparation to making a loop purchase, and I'm sure others who may be looking for the same information.

Happy to hear your satisfaction Chris...Enjoy your loop there, it's a good one!

Hi Ross

I should have bought this loop first a long time ago. I bought the ALA-1530 because I wanted an all purpose loop for HF and MW. I listen to shortwave, usually from about 3 MHz up to about 15 Mhz and I also like to listen to late night talk radio on AM. I get a kick out of how many stations I can pick up from around the country where I live at night. I had my Pixel up on a mast about 20 feet up on a rotator. I am going to put the Wellbrook up in the same place soon. I can't go any higher because of the power lines behind my property. I'll try and put up a picture when everything is all mounted again.

I don't have a license so I cannot answer your questions regarding a transmitting antenna. I live out in the middle of nowhere in Colorado where there really isn't anyone that I can learn from so I just stick to the shortwave for now.

Chris

Hey Chris,

Thank you for your reply...appreciated.
If you wish to move ahead and try to get into amateur radio, google ARRL. This is an organization all about amateur radio, and if & when you have any further questions or wish to move ahead feel free to contact me, I will offer you what help I can..I'm 57 here and forced to be disabled after working all my life then due to multiple back surgeries and related issues, & then get a supprize leukemia diagnosis.uggh...

Love all things radio, and first started listening to AM, and tried to get all 50 states. I also really enjoy nighttime AM talk radio.
I had driven my van from Cleveland,Ohio down to Corpus Christi, Texas and back eight times on our family vacations. After all day driving my wife & daughter would fall asleep and I would listen & tune the AM stations as I drove across the country, when I hear the late night AM talk radio now, it takes me back to those days!..We ended up moving to Corpus, but moved back to Cleveland as my wife became homesick.

After AM listening, I went to shortwave listening, CB, then took part in 11 meter sideband in the very early 70's, keeping on the illegal theme, I then wired up an military ARC-5 transmitter and ran a bootleg AM radio station, transmitting pretty far even into Canada. Then went straight and got my novice license in ham radio in 1973.

I think you would enjoying transmitting as much as you do listening, there is something in amateur radio that should match your interest!

Back to the loop...sorry for getting off course there...Looks like I'm going to purchase the 1530 as you did. I have done lots of research and you picked a winner, happy to hear of your success. I will also use a rotor, the loop is not so much directional as it having a quite sharp null.
The rotor will allow you to null out interference as well as other stations, at times you can tune in a AM station, then on the same frequency turn your rotor around and the station you were listening to will fade out and the loop will pick up another station...right on the same frequency!...Very cool!

Thanks again for your information on your wellbrook loop, with the new design you should enjoy years of enjoyment. Keep the group updated, and your pic's would be enjoyed by many.

Have good evening friend...

Terk AM loop at Amazon.com
Here is a place you can buy yourself a TERK AM loop antenna, even some other stuff that is kind of off topic to talk about. 73
http://www.amazon.com/exec/obidos/ASIN/B000069EUW/qid=1075080062/sr=2-1/ref=sr_2_1/102-8712984-4397719

WL1030 by the late Maartenhagg. Plans placed on this website by his friends in his honor.
http://wl1030.com/content/

C Crane Company
They sell the Justice AM Loop Antenna, Select A Tenna, Terk AM 1000
http://www.ccrane.com

Kiwa Electronics
Kwia makes the best products for you and your radio equipment, and also improves things that needed improvement a long time ago.
http://www.kiwa.com

Stormwise Ferrite Rods
Get some huge ferrite rods and a converter to go along with its, heck it even comes with project book.
http://www.stormwise.com

Universal Radio Company
They sell all sorts of loops big and small for LW/MW/SW and VLF also 10 kHz to 15 MHz
http://www.rffun.com

ALA-1530
Find the best UK LF/MF antenna here.
http://www.wellbrook.uk.com/

AOR
This is the site that sells the AOR loop
http://www.aorja.com/ant-e.html

Kiwa Electronics
The maker of the air core loop antenna and other useful items that you may want on your wish list.
http://www.kiwa.com

LF Engineering Company
A group of engineers, who make products for VLF/LF listening even ELF loops!
http://www.lfengineering.com

Select A Tenna by Intensitronics Corp
The maker of the select A tenna, a great AM loop antenna that is a little bigger than the terk
discontinued

Terk Technolegies
The maker of the best sold AM and I use also called the AM-1000 AM loop antenna, there is also technical information on how it works.
http://www.terk.com

Torus Tuner Loop Company
A very specially made loop that is almost as big as a hula hoop
discontinued

GRAHN (Germany) Specialized Loop Antennas for MW and SW Reception Contributed by radiohighfreq

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10704. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-08-01 11:30:14 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10704

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Loyd wrote:

"I heard some one on the air who indicated they were using a Fractional Loop antenna."

If I heard that, I would seek clarification.

Until that, I would guess that it might mean either:
- A Fractal antenna of some kind, or
- A loop antenna that is a fraction of a wavelength long, also known as a Small Magnetic Loop antenna.

I've never heard of a Fractal Loop, but I suppose they could exist. Fractal antennas are somewhat controversial, as to whether or not they actually do anything special, other than just look pretty and perhaps make big bucks for the people who make and sell them. Fractal antennas are apparently used in cellphones, and that may be their niche application. I have not heard much about them in significant use elsewhere. There's a guy named Nathan Cohen who has been a big proponent of fractal antennas, though these days his company (Fractal Antenna Systems Inc.) seems to be more interested in researching meta-materials and 'cloaking' devices, than antennas. Mr. Cohen has been the target of much ridicule in years gone by.

Small magnetic loops can be either homebuilt or purchased. They are the magnetic equivalent of a very short dipole. They tend to have very large currents and voltages and very narrow bandwidths and require a lot of attention to keep the losses down. Most small loops are used on the higher HF bands, not 80, but yes they can be used there too. Losses tend to go up (and bandwidths down) as you go towards the lower frequency HF bands, unless you scale the antenna dimensions up accordingly. Most homebuilt small transmitting loops require a vacuum capacitor, which is a kind of variable capacitor normally found in high power transmitters. They can better withstand the large currents and voltages (many 10s of KVs) and keep the I*R losses down.

The AlexLoop is one of the less expensive commercial small loops.

I made a fractal antenna for HDTV. Works great.. I picked all the stations in the NY area.

Essentially a dipole antenna folded down. (UHF) see attachment. I guess if it was resized..... but for lower freqs it would be much larger, using the same design.

Best Regards
Phil

10707. Fractional TURN loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-08-01 21:33:16 UTC
From: Richard (Rick) Karlquist
Topic: 10701 Message: 10707

I believe that I commented in this group recently that the
Mobius loop developed by the military and copied by Pixel can be
considered to be a fractional TURN loop (IE 1/2 turn). (Not a
"fractional loop" as you said.) I coined that
terminology as it applies to Mobius loops.

What I mean by this is that an N turn loop has N times
the open circuit voltage compared to a 1 turn loop.
A Mobius loop has 1/2 as much open circuit voltage
compared to a 1 turn loop, so it could be considered
a 1/2 turn loop.

As of course they are commercially for sale by the
company the took over from Pixel (I forgot the name).

Understand the use of "HDTV" as any part referring that there is something special needed to receive "HDTV" signals is false and inaccurate. The receiving antenna does not care what type of information is being sent, only the frequency. A regular antenna made for analog signals at the same frequency would work just as well. The Fractal loop is just a full wave loop (Adjusted length according to interaction of folding) allowing it to be more compact and smaller. Using fractal design allows for a "quad" type antenna to have similar gain in a small size. Also it works somewhat different on F/B and forward gain patterns. Magnetic (Fractional loop) is a different thing all together. There are hundreds of articles and books available for reading.

Hello Phil,

Unfortunately your email got caught in my spam filter, and the attachment got stripped off. Could you post it again?

Thanks a bunch,

Brian Burns

I made a fractal antenna for HDTV. Works great.. I picked all the stations in the NY area.

Essentially a dipole antenna folded down. (UHF) see attachment. I guess if it was resized..... but for lower freqs it would be much larger, using the same design.

Best Regards

Phil

If I heard that, I would seek clarification.

Until that, I would guess that it might mean either:

- A Fractal antenna of some kind, or

- A loop antenna that is a fraction of a wavelength long, also known as a Small Magnetic Loop antenna.

I've never heard of a Fractal Loop, but I suppose they could exist. Fractal antennas are somewhat controversial, as to whether or not they actually do anything special, other than just look pretty and perhaps make big bucks for the people who make and sell them. Fractal antennas are apparently used in cellphones, and that may be their niche application. I have not heard much about them in significant use elsewhere. There's a guy named Nathan Cohen who has been a big proponent of fractal antennas, though these days his company (Fractal Antenna Systems Inc.) seems to be more interested in researching meta-materials and

'cloaking' devices, than antennas. Mr. Cohen has been the target of much ridicule in years gone by.

Small magnetic loops can be either homebuilt or purchased. They are the magnetic equivalent of a very short dipole. They tend to have very large currents and voltages and very narrow bandwidths and require a lot of attention to keep the losses down. Most small loops are used on the higher HF bands, not 80, but yes they can be used there too. Losses tend to go up (and bandwidths down) as you go towards the lower frequency HF bands, unless you scale the antenna dimensions up accordingly. Most homebuilt small transmitting loops require a vacuum capacitor, which is a kind of variable capacitor normally found in high power transmitters. They can better withstand the large currents and voltages (many 10s of KVs) and keep the I*R losses down.

The AlexLoop is one of the less expensive commercial small loops.

"the attachment got stripped off. Could you post it again?"

Here was the link to the attachment:

https://groups.yahoo.com/neo/groups/loopantennas/attachments/267137820

If that doesn't work, go to the group's main webpage, then click on More, then Attachments. The one (currently) at the top of the list is "Re: [loopantennas] (unknown) <https://groups.yahoo.com/neo/groups/loopantennas/attachments/267137820>". Click on that. Now you should see an icon for the PDF file, ready to be opened or downloaded.

All this stuff about "HDTV" is sure to cause dumbed-down confusion. Not only is it meaningless with respect to an antenna, but in some circles, "HDTV" has come to be synonymous with the remaining UHF TV channels ... which is unfortunate because some TV stations are still on VHF channels. Not many, but a few. I'm not referring to the "channel number" either (which is now meaningless, thanks to HDTV), but to the actual frequencies used.

But I digress from the subject of loop antennas.

Understand the use of "HDTV" as any part referring that there is something special needed to receive "HDTV" signals is false and inaccurate. The receiving antenna does not care what type of information is being sent, only the frequency. A regular antenna made for analog signals at the same frequency would work just as well. The Fractal loop is just a full wave loop (Adjusted length according to interaction of folding) allowing it to be more compact and smaller. Using fractal design allows for a "quad" type antenna to have similar gain in a small size. Also it works somewhat different on F/B and forward gain patterns. Magnetic (Fractional loop) is a different thing all together. There are hundreds of articles and books available for reading.

I think you mean Fractional Wave Loop Antenna which differs from a Small Magnetic Loop Antenna in that a SMLA is 1/10 wavelength or less and a FWLA is usually closer to 1/4 or even 1/2 wavelengthGoogle search brings up a lot of information using the proper term

Ignore those who told you you were using the wrong term here, they were (mostly) wrong and were just ignorant of a different type of loop antenna

This looks to me like a good place to start

The concept of helically loading a loop is complete nonsense.
The last thing you want is additional inductance and RF resistance.
One of the "advantages" touted here is reduction of cost and weight
by replacing solid copper pipe with plastic pipe wrapped with
copper foil. That much is fine, but if that is what you want
to do, you should simply run the foil in a straight line along
the length of the plastic pipe so it is an electrical equivalent
of copper pipe. To whatever extent these antennas "work", they
would work better without helical loading.

Also remember that no matter how you construct it, a small loop
will have a combination of poor efficiency, extremely narrow
bandwidth and/or limited power handling. Helical loading does
nothing to change this fundamental fact, and actually makes
it worse.

"The concept of helically loading a loop is complete nonsense.

The same can be said about a loading coil at the base of a shortened vertical.

And yet people do it all the time. One might say it makes HF mobile possible.

It is just an aide in achieving a better impedance match with a non-resonant antenna.

The flip-side is that one can fool oneself into thinking that a trick actually improves an easily measured property, such as bandwidth. Indeed the bandwidth does go up if you do something that adds loss. (FYI, I do not believe that wider bandwidth is something claimed for Rich's helically loaded small loops.)

As an aside, I've been trying to understand the figure-8 configuration that some small loop builders seem to be using, and whether there is anything special to it or if it's just wasted work.

On the plus side, Rich Fusinski and others seem to have one heck of a lot of fun making and using those loaded loops. Why spoil their fun? :-)

I agree completely. It is perhaps instructive to observe the fundamental error that leads the designer to his erroneous claim that a helically-wound loop is more efficient (!) than a solid-conductor loop of equivalent loop diameter. From the above-referenced page we see the reasoning behind the helical loop:
http://antennastealth.com/calculate-a-helical-loop.html
http://antennastealth.com/calculate-a-helical-loop.html . Note the following misleading statement: "If we divide 32.97 feet of copper by 3.14 we get 10.5 feet which electrically makes the 6 foot loop inductance value equal to 10.5 feet."

If you follow along the computations shown on that web page, you can see that the author is:

(a) Computing the total length of copper strap wound into a helix around the circular loop support. (Obviously, the length of the strap will be longer than the circumference of the circle formed by the physical loop support around which the strap is wrapped, because the strap is forced to wind its way around the small diameter of the support tube on its way around the large circular support.)

(b) Computing the diameter of a hypothetical circle that could have been formed if the entire length of the helically-wound copper strap would have been unwound and formed into a large circular loop with no helical winding or other meandering of the conductor. (Obviously, this hypothetical circle will be of larger diameter than the physical diameter of the circular loop support.)

and finally, the fatal error,

(c) Plugging in this hypothetical "diameter of a loop that could have been formed, but was not formed, by the helically wound strap" directly into AA5TB's loop calculator in the field for the physical loop diameter, which then yields unphysically high values for radiation resistance and efficiency that are based on the hypothetically larger loop diameter, that does not reflect the physical loop diameter.

In other words, for a given physical loop diameter in physical 3D space, the helically wound loop is using a longer total conductor length that has been packed into the same physical 3D space. The idea that this increases the efficiency of a small loop is -- again -- nonsense, at least to anyone who understands how small loops radiate (phase difference between opposite sides of the physical loop leading to incomplete field cancellation). Of course, attempting to point this out to the helical loop enthusiasts is an exercise in

futility.

I've resigned myself to taking the same stance. I have nothing against antenna experimenters having fun, but still, it is annoying to see extraordinary, unsupported claims boldly and confidently being made, that contradict hundreds of years of evidence-backed electromagnetic theory and practice. Such is the Internet.

Beware the conclusions of Mr. Duffy. Best to bring along your lawyer and experimental physicist when reviewing his work. While he may be correct in a large number of circumstances, it is in the "fine details" (in the assumptions in any given analysis) which leads to incorrect results in the overall.

Also, there are limitations in the so-called 'loop calculators'; no one has addressed this particular issue that I am aware of by rigorously verifying calculated results against measurements. I find the calculators are erroneous (at a minimum) when loop circumferences approach 1/4 Lambda.

It is a simple enough exercise to calculate skin depth for a given material then use that in calculations for effective loop 'resistance' that I try to avoid the calculators when looking at potential losses in loops.

For instance, for round materials:

Clemson Vehicular Electronics Laboratory: Round Wire Resistance Calculator

In regards, to helical loop advantages, it does serve to reduce the capacitance required to achieve resonance, given a particular loop diameter, a factor which could be used to advantage to meet certain goals (e.g. restricting loop size for practical-use reasons.) I have experimented with inserted in larger loops (at low frequencies) to reduce the amount

of capacitance required to achieve resonance.

Another Andy,

I have achieved roughly twice the Q in a coil by switching from PVC to HDPE (polyethylene) as coil forms at 7 MHz. The losses are due to dielectric (electric field) losses, so the loss in a helically-loaded loop where the mag field is a factor might not present the same losses. In the vicinity of the tuning cap would be the concern. Also, PVC is subject to breakdown and ignition under HV and short creep-paths or where it is depended on for 'insulation'.

If one looks at the technical loss figures (DF, 'loss tangent' etc) for PVC vs HDPE one can see why dielectric losses are notable.

But isn't winding the copper strap around the PVC support in essence the same as winding copper wire around that PVC support? If the latter suffers from dielectric losses, wouldn't the former as well?

Anyway, the claim that adding loading inductance to a small loop antenna can increase the loop's efficiency (by supposedly increasing the radiation resistance without increasing the physical loop diameter, and by supposedly reducing the conductor losses below those of a solid conductor) is supported neither by logic nor by any quantitative, repeatably-measurable, and falsifiable data. For practical construction reasons an argument might be made for helical winding, but not for efficiency. At least not with any data that's been shown so far (and no, QSOs don't count).

Not the same. My turns were adjacent using 10 ga. Teflon jacketed copper on a 4 inch diam form versus 3" copper strap comprising a loop where just a fraction of the 'volume' is occupied by PVC material.

Look at the dv/ds (delta voltage / delta distance) in the two cases and where the electric fields lie.Maybe if you sketched out where the electric lines of flux appeared it would help visualize this for the two cases.

BTW, where is the claim made that this increases the loop's efficiency? This appears to be a repeated meme by some, but does not appear on the primary source's web page on this subject.

On the subject of verifying antenna claims, I have seen only one gentleman on the 'net who has done valid comparative antenna testing, and that was using WSPR and two transmitters on two different WSPR freqs (on the same band, of course) to assure both antennas saw identical prop conditions during each of the 2 minute transmit cycles.

Switching between two antennas during a QSO can easily 'show up' differences of 6 to 10 dB, but with changing fade characteristics even this can be iffy if an insufficient number of 'samples' are taken.

It is well documented that PVC has a dissipation factor of around 2%.
If you don't believe that, measure the loss in vinyl zip cord used
as RF transmission line.

If used as a coil form, it is not so straight forward to determine
the effect of loss due to the PVC form. It doesn't cause loss
due to the dominant magnetic fields, but only the electric fields.
The coil can be thought of as a helical transmission line, so
there will be some additional loss due to dielectric loss in the PVC.
This may or may not be significant compared to the copper loss.

It is also worth noting that skin effect causes the RF current
to flow mainly on the edges of the copper strap, thus wasting
most of the copper. Round conductors have lower copper losses
because they don't have edges. This forces the current distribution
to be fairly uniform for maximum utilization of the copper.

Thus the truth is somewhere in between "q-killer" and "no detectable
loss".

It is a repeated meme by the antenna inventor.

Quote by K8NDS at http://www.eham.net/ehamforum/smf/index.php?topic=85149.50 http://www.eham.net/ehamforum/smf/index.php?topic=85149.50 :"if you understood my design; it works as good as a full sized mag loop being at least 30% smaller in diameter then loop calculations".

Quote by R. Fusinski at https://www.youtube.com/watch?v=2YpyLAULKqg https://www.youtube.com/watch?v=2YpyLAULKqg: "This magnetic loop antenna is about 50% smaller in diameter then a text book magnetic loop. The performance is outstanding, it compares or is better then a 1/2 wave dipole mounted 1/2 wave above ground."

Quote by K8NDS at http://www.eham.net/articles/26572 http://www.eham.net/articles/26572: "I have designed a 6ft diameter loop that has the characteristics of a 80 meter loop that seems to emulate a 10 to15 ft diameter loop of a single conductor [...] I have raised the radiation resistance considerably while only raising the IR losses slightly".

Quote by K8NDS at http://www.hlmagneticloopantennas.com/ http://www.hlmagneticloopantennas.com/: "By implementing a helically wound design a 6ft diameter 80 meter text book loop seems to emulate a 10 to 15 ft diameter loop of a single conductor. [...] This allows the use of a thin flat copper conductor which provides more surface area then a heavy copper pipe while still providing a large surface area of RF skin depth. At the same time the radiation resistance is raised considerably while only raising the IR losses slightly. [...] The result is a two part gain; the same length of copper conductor that is required for a 10 ft diameter loop equates to similar performance wound on a 6 ft diameter substrate; thus reducing the size, weight and cost while still retaining the performance."

Quote by K8NDS at https://groups.yahoo.com/neo/groups/Helically_Loaded_Mag_Loop/conversations/topics/161 https://groups.yahoo.com/neo/groups/Helically_Loaded_Mag_Loop/conversations/topics/161: "My new 40 to 15 meter design, remember even though only 39 inches uses 22 ft of conductor 3 inches wide. If you use 22 ft circumference conductor as a reference plus the helix adds Z to it. You then come up with at least equivalent diameter of 7 ft. [...] So going back to 7 ft, 7 ft gives us around 81% efficiency."

And again, all you have to do is try to follow along with the calculations at http://antennastealth.com/calculate-a-helical-loop.html http://antennastealth.com/calculate-a-helical-loop.html and you'll see where a fictitious hypothetical larger loop diameter (that could have been formed, but was not formed, if the helix were to be unwound and formed into a larger-circumference loop) is incorrectly used as the physical loop diameter in AA5TB's loop calculator, which gives unrealistically large

values for radiation resistance and efficiency. The erroneous calculation (and the underlying logic that leads to it) shown on that page goes a long way towards explaining the questionable claims made about the helical loop's efficiency.

And, of course, you have verified by experiment and experimental means that each of those claims is untrue? Simply citing the results of numerical 'design' recipes is not sufficient in explaining the reason the concept fails in physics.

I wasn't aware of the claims made on the Youtube video, only referencing his website where his claims are a little more rational (doing a keyword search on "efficiency" on www . hlmagneticloopantennas . com); no claims of performance equalling an 80 meter dipole 1/2 wave above ground for instance. Perhaps in producing the website at a later date a more objective view was taken on the subject.

You are aware of the mechanism by which loops work, with the EMF being differentially induced in the two arms as the incoming RF wave propagates forward first encountering the one arm of the loop followed by an encounter with the second arm? With the added 'length' of each arm by helically coiled copper strap, does this in any way affect the induction of EMF in the two arms? The effect of slight additional delay in summing the two arms is also a factor, as the upper and lower 'conductors' in the loop are also helical conductors.

BTW, have you by any chance sketched out where the lines of electric force exist on the helical loop antenna versus a tightly wound coil vis-a-vis PVC coil forms and antenna support forms?

And, of course, you have verified by experiment and experimental means that each of those claims is untrue? A general note about testing claims. There are two criteria any claim must meet: to be internally logically consistent and to not contradict known experimental results. If a claim fails any of these, there is no point in investigating it, it would be a wasted effort.

With the added 'length' of each arm by helically coiled copper strap, does this in any way affect the induction of EMF in the two arms?
No, it doesn't. The total EMF is an integral over all small elements of the loop. The orientation of the element is important: the function under the integral is a vector multiplication of the direction of the element and the magnetic field vector. If you do the math carefully, the total EMF does not depend that much on the "fine structure" of the loop conductor, especially for small loops. The only factor that has the proportional effect on EMF is the loop area.

Mike, thank you for answering for the other gentleman, but, I would like to see how this squares with the depictions in Keen 1927 (reference figures 6 through 9) on the subject of loops and the mechanism for inducing a signal into a loop from a propagating wave.

I have no doubt in the elementary form of a loop what you state holds true. One should also at this point realize that the Keen material has merit in that his approach provides for, or accounts for the 90 degree difference in 'observed phase' between the signal induced into an 'open aerial' (IOW a vertical or sense antenna) versus a loop, and is the reason why in direction finders of yesteryear circuitry was incorporated in the receiver to put 'in phase' the signals seen on the 'sense' antenna and the 'loop' antenna.

We are all familiar with this axiom (based on measurement and physics), I assume (from wiki on antenna aperture):

"In general, the aperture of an antenna is not directly related to its physical size."

Or this from W8JI:

"For example a 1/2 wave long dipole in freespace has a capture area of about .13λ^2. This means a lossless freespace dipole has an Ae of approximately .13 square wavelengths. This effective aperture is about 100 times larger than the actual physical area of a thin wire dipole antenna. Energy is extracted from an elliptically shaped area slightly longer than the dipole and about 1/4 wave diameter at the center."

Has this 'principle', for a tuned wire/conductor antenna:

. . . . . antenna aperture > physical area

been ignored as it applies to loops in general?

Jim

No, I have not. The antenna inventor making the claims bears the burden of proof.

For a given small transmitting loop of diameter D, the claims of (a) being able to the reduce the diameter by 30% while maintaining identical performance and (b) being able to significantly increase the radiation resistance above that of a solid-conductor loop through the helical winding are startling claims and, if supported by quantifiable, repeatable, and falsifiable data such as that obtained through controlled field strength tests, would deserve further investigation. For me, only insufficient and inconclusive data and methods have yet been presented, that do not yet warrant that level of investigation.

That is a very good question, and is one that I raised 2 years ago in the eham.net forum here:

http://www.eham.net/ehamforum/smf/index.php/topic,85149.msg622196.html#msg622196
http://www.eham.net/ehamforum/smf/index.php/topic,85149.msg622196.html#msg622196

There I asked, "Is it conceivable that the helical winding alters the current flow such that the flows in opposing conductors 'fight' each other to a lesser degree? [...] I suppose one would also need to consider current flow within each small helical turn and between turns as well".

N3OX conducted a NEC-2 analysis and replied:

http://www.eham.net/ehamforum/smf/index.php/topic,85149.msg622236.html#msg622236
http://www.eham.net/ehamforum/smf/index.php/topic,85149.msg622236.html#msg622236

I will quote the main conclusion of his NEC-2 analysis:

N3OX wrote: "There's a lot of field cancellation of each small turn in terms of the influence on the diametrically opposite side of the loop, so the main important component of the current is still the 'axial' or 'along the big loop' component. The 'around the turns'

component will mostly cancel way over on the other side of the big loop, just like a magloop mostly cancels in the far field. So there's not much effect there."

There is of course the argument that NEC-2 cannot properly model this sort of a structure. I went a step further and created a 3D model of a helical loop antenna wound with a thin strap. I uploaded an image of my 3D model to the Files section of the loopantennas group under the filename "helical-loop-3d-model.jpg". The eventual goal was to import this into a 3D electromagnetic field solver that uses the Finite Difference Time Domain (FDTD) method, to compute the structure's radiation resistance and ohmic loss, and also to enable the visualisation of the RF current flow along the strap. These efforts are stalled at this point because it takes considerable time and effort to prepare the model structure for import into the FDTD package, as well as to understand the simulator limitations (FDTD seems somewhat weak when it comes to simulating skin effect, requiring a ridiculously fine-grained mesh) and to gain confidence in the simulated results. I find it difficult to motivate myself to continue further serious investigation of the antenna because the basic claims of performance gains and the proposed theory of operation haven't crossed my personal threshold of credibility for requiring further scrutiny.

If someone is seriously interested in conducting a 3D electromagnetic field simulation of a helically wound loop, I am willing to make my 3D model files available - but again, I don't expect any startlingly high efficiency from the simulation - just a slightly lowered efficiency due to the increased current path length. I'm sure many hams are happy with that level of performance.

I read somewhere a brief comment by W8JI that the current distribution on a strap changes when you form the strap into a coil - which only makes sense. I seem to recall W8JI was saying that the current flow on the strap is forced back towards the center - but I may be remembering incorrectly. Unfortunately I can't find the comment now - it was just a brief comment as part of an online discussion.

G3RBJ also has a paper that may be of interest, though I haven't gone through it closely: http://g3rbj.co.uk/wp-content/uploads/2013/08/The_HF_Resistance_of_Single_Layer_Solenoids_2.pdf http://g3rbj.co.uk/wp-content/uploads/2013/08/The_HF_Resistance_of_Single_Layer_Solenoids_2.pdf

Section 4 on page 6 is titled "4. RESISTANCE OF A COIL WOUND WITH THIN CONDUCTING STRIP".

PVC is lossy when exposed to microwaves. If you put a piece of (grey)
PVC in a microwaves oven (running at 2.4 GHz), you'll see that its
temperature is increasing.

However I have some doubts about any PVC losses at very low frequencies ...

The LF Experimental license holders are using PVC as core for very large inductors. These run at high power levels (2KW). I have one matching inductor for my 74KHz antenna that I have run at over 1KW and have seen no signs of poor Q. The Q may be somewhat less than air but not near as bad as some state.

G3RBJ has recently (2013) cast some doubt on some of the results (the proximity effect results) presented in that 1971 Smith paper:

http://g3rbj.co.uk/wp-content/uploads/2013/08/The_HF_Resistance_of_Single_Layer_Solenoids_2.pdf http://g3rbj.co.uk/wp-content/uploads/2013/08/The_HF_Resistance_of_Single_Layer_Solenoids_2.pdf

Quote from G3RBJ: "Taken together the above two graphs place considerable doubt on Smith's data, and suggest that his measurements were of a coil rather than the isolated conductors as he intended. [...] Smith's data for multiple parallel isolated conductors is not at all in agreement with the theory given here. However, if it is assumed that Smith's measurements are of a coil, rather than isolated conductors as he intended, then his measurements are consistent with the theory."

For more information, search the G3RBJ paper for the word "Smith".

If you will take note, the PVC 'molecule' exhibits polar characteristics, much like water (water is a 'polar' molecule) and subject to dielectric heating when subjected to rapidly changing high-value electric fields. At lower frequencies the heating (the loss) may not be as great as at say 7 MHz (where I saw decreased Q and heating even) as it is at 60 Hz or 74 kHz.

pvc.org: "PVC has an amorphous structure with polar chlorine atoms in the molecular structure. Having chlorine atoms and the amorphous molecular structure are inseparably related. Although plastics seem very similar in the context of daily use, PVC has completely different features in terms of performance and functions compared with olefin plastics which have only carbon and hydrogen atoms in their molecular structures."

From wiki:

Electrical properties

PVC is a polymer with good insulation properties but because of its higher polar nature the electrical insulating property is inferior to non polar polymers such as polyethylene and polypropylene.

As the dielectric constant, dielectric loss tangent value and volume resistivity are high, the corona resistance is not very good, it is generally suitable for medium or low voltage and low frequency insulation materials.

10740. Modeling inductively loaded loop (was Re: [loopantennas] Re:)

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-08-29 20:15:13 UTC
From: Richard (Rick) Karlquist
Topic: 10701 Message: 10740

There has been some discussion about the difficulty of modeling a helical loaded loop. In the case of a helically loaded vertical, we know that there is nothing magic about helical loading compared to lumped element inductor loading. IOW, a series of lumped coils will do much the same thing as helical loading.

EZNEC, according to the manual, can model square loops down to 0.05 wavelength perimeter, with one segment per side. I modeled a .1 wavelength loop, putting a current source in one side and loads in the other three sides. If there were anything to the helical loading concept, I should be seeing similar effects in this simple model. I included a receiving antenna 10 wavelengths away consisting of a half wave dipole loaded with 1000 ohms. The wires were 0.001 wavelength diameter. Modeling was done in free space.

I started with the loads set to zero, and the loop modeled as expected, 1.6 dBi gain, 0.013 ohms driving resistance. Then I tried setting the loads to various values of inductive reactance. As they were increased, the driving point resistance increased. For example, with three 100 ohm loads, it was 0.024 ohms. The gain with this loading decreased to -0.48 dBi. The power from the current source, of course, roughly doubled. However, the received power in the receiving antenna only went up about 20%. The loading coils decreased the efficiency. Going beyond 100 ohms results in the loop beaming broadside and the polarization flips. Have the helically loaded loops claimed to beam broadside?

Now here is what I think the misunderstanding is: you might think that since the driving resistance nearly doubled, then the "radiation resistance" also doubled. Then the helical loaded loop would seem to make sense. However, this is based on a misunderstanding of the definition of radiation resistance. The effect of the loading acts more like using multiple turns on a loop to increase the driving resistance. That is the same as simply putting a transformer between the source and loop, which of course has no effect on efficiency. How do we know this? Because the EZNEC model shows a decrease in efficiency when the loading is added.

I tried adding resistance to account for a coil Q of 1000. This additional resistance only served to decrease the efficiency by over 10 dB. Thus real world coils are either too low in inductance to do anything at all, or their resistance adds significant losses, even with a Q of 1000. We can be quite certain that helically wound strap does not have anything approaching this kind of Q.

Rick, since I have seen differences between 'real life' and what NEC-2 based MOM modelers yield regarding loop antennas, I don't have quite the 'faith' you do in their infallibility. Were it not for the fact that a helical loop is not a simple planar (2-space) structure but occupies a non-trivial amount of volume in 3-space I would still like to see a basis-in-physics explanation outside of the reliance of the usual modeling programs.

Yet to be explained as well is the phenom where Ae > physical size as it may apply to loops.

It would be very easy to build a loop and put in lumped element inductors to experimentally verify that magic happens or doesn't happen. But consider this thought experiment. If the loop radiation resistance is only 0.013 ohms, any coils you insert with more than a few dozen ohms of reactance add significant losses relative to 0.013 ohms. But a few dozen ohms of reactance has negligible effect on anything. A helically wound strap is not a free lunch. The total conductor path is longer and narrower, hence increasing losses.

It has been experimentally verified countless times that helically loaded verticals have no special properties compared to conventional loading coils. Why should it be different with loops?

>
> Yet to be explained as well is the phenom where Ae > physical size as it
> may apply to loops.

What is it that hasn't been explained? Lots of antennas have Ae > physical size. That doesn't mean that helically wound loops have additional Ae. Where physical size comes into play is that you cannot simultaneously have small physical size and high efficiency without extremely narrow bandwidth and limited power handling due to the necessarily high loaded Q. The proof of this is independent of how the antenna is constructed. The article originally cited makes no mention of bandwidth.

Perhaps in producing the website at a later date a more objective view was taken on the subject.
>
>
> You are aware of the mechanism by which loops work, with the EMF being differentially induced in the two arms as the incoming RF wave propagates forward first encountering the one arm of the loop followed by an encounter with the second arm? With the added 'length' of each arm by helically coiled copper strap, does this in any way affect the induction of EMF in the two arms? The effect of slight additional delay in summing the two arms is also a factor, as the upper and lower 'conductors' in the loop are also helical conductors.

From: dx11
Topic: 10745 Message: 10745

Theory is nothing else than a way of describing reality. Theory makes it possible to predict the behavior of a device before it exists and makes it possible to explain its behavior when it exists.

“Make it” and “” Measure it” are sensible and even necessary stages in any product development project.

But before the “Make it” phase there is a phase where it is decided what to make, the design phase.

That phase is based on some theory even if you’re not aware of it.

After the “measure it” there is an evaluation phase where it is analyzed why the device is performing as it did in the test and why it is performing better or worse than a different design.

This also is based on theory.

So the good application of theory (part of that is modelling) is absolutely necessary in the development of new products that perform better than the previous products.

Without theory there is no innovation, no improvement.

So if you don’t want to apply theory, don’t make anything new, it is a waste of time. Just copy what others have designed (with the use of theory).

Regards,

Cor Beijersbergen PA4Q

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10747. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-09-01 09:14:09 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10747

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

Steve Greenfield

10748. SWR trouble with MFJ 1788 loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-09-02 19:40:02 UTC
From: ve3wdm@...
Topic: 10748 Message: 10748

I have been off the air for the last week or so (off the air using the MFJ 1788 that is) today I wanted to use it and it's set up on my balcony. The problem is the SWR on 15 and 20m I am only able to get the SWR to 2.0.1 where in the past I could almost get it flat. The weather is very humid out and I was wondering if that could be the issue as nothing else has changed in the antenna system.....other than not using it for a week?

Rick,

It has still not been explained how Ae > physical_size on any antenna, let alone loops.

The only thing that has been 'explained' is that the phenom exists, and that is not an explanation in physics as to _why_ the phenom exists nor how it comes about. Just grand 'hand waves' exist as far as I have seen. Even the MIT online EM course video lectures do not address this issues (or maybe I missed that part of a course). And please, save the lecture about the trade-off for B-E-S (BW, EFF and SIZE; pick any two the the 3rd is a given) for the newbies.

The only material remotely addressing this is far above the pay grade (and ed level) of most 'ham and egg' operators and lies in the field of actual physics, e.g. as this paper:

“Resonant energy absorption and the CTF hypothesis“
Michael Ambroselli ; Chandra Roychoudhuri
Proc. SPIE 8832, The Nature of Light: What are Photons?
V, 88320T (October 1, 2013); doi:10.1117/12.2024126
http://proceedings.spiedigitallibrary.org/proceeding.aspx?articleid=1747250
http://proceedings.spiedigitallibrary.org/proceeding.aspx?articleid=1747250
Abstract
Antennas in resonant circuits can present an effective energy absorption cross-section much larger than its physical dimensions to the impinging EM waves.
Similarly, atoms can absorb energy from fields with energy densities so low that the atom must have an effective interaction cross-sectional diameter on the order of tens of microns. It appears that resonant energy absorption exhibits a sort of “suction” effect by the absorbing dipole, or a “pushing” effect by the field, or a combination of both. This allows the field energy to converge from a larger volume into a smaller region. We will argue that this effect may actually correspond to the field preferentially directing energy into such resonant systems, and discuss how this provides further evidence for the utility of our proposition of a universal, complex tension field (CTF). We have proposed that CTF can support propagating field gradients, like EM waves, as well as resonant, localized and self-looped oscillations representing various particles. Different gradients in the CTF, generated by different kinds of particle-oscillations, represent the various forces experienced by particles within each others’ physical domain. Even time emerges as a secondary property.

Perhaps it will help if you realize that the aperture is just a number calculated from the way the antenna picks up the signal. It does not represent the real size of the antenna. I believe it is very analogous to numerical aperture (NA) in optics which also is not truly the size of the lens but a measure of the amount of light it can pick up. For example for some applications a lens is used with a liquid between the lens and the object being looked at. The liquid does not increase the size of the lens but increases the NA.

Optics is not electronics so maybe this is not a great analogy, but perhaps this can help you.

Rick,

It isn't 'help' I'm seeking. It's an explanation in physics I'm looking for to explain observed phenomenon. Perhaps this distinction has not been made clear. Now it has been. The paper I referenced earlier is in the vein of what I am seeking (and obviously found), as opposed to continued 'grand hand waves' by most antenna experts and physicists even.

Maybe it would help you to visualize what I'm getting at - If you have ever seen a waveguide to coax adapter ask yourself how it is that the little 'probe' is able to so efficiently 'channel' all the RF from out of the waveguide and into the coaxial element, and do so with low insertion loss and a respectable 'return loss' (SWR or 'match') as well.

There is more going on with 'simple' antennas even (e.g. dipoles and verticals) than is commonly conveyed by articles and discussions on these subjects. At the 'ham and egg' operator level such detailed and nuanced understanding is obviously not necessary, but we have gone beyond that as we dissect various forms of tuned loops and understand what determines their theoretical limitations from the stand point of physics.

Hello,

I have built a half delta flag antenna, 13ft x 9ft, but I am not very happy with the nulls.
I have tested a 1070 Ohms terminating resistor and tomorrow with a 950 Ohms.

I suppose that when adjusting the resistor the MW receiver must be in the center of the band or at the end?
Surfing the web I have seen that some people use vactrol but this could cause intermodulations.

I have in mind to build a rotatable flag,a 9ft x 6ft rectangular shape since I will not be stuck in a position.

So, would you recommend me to use a vactrol resistor or try with different fixed values, I am using a potentiometer.

Thank you very much
Regards

read article yesterday where fellow used relays to remote select resistors for his flag antenna, i guess depending on frequency and position. He stated the use of vactrol was too expensive and too fussy. Possibly using adjustable potentiometers and selecting them remotely may be they way to go. I plan a flag for 160 and 80 soon, so I will try it.

Use a remotely controlled vactrol. Built one using rad shack led and photocell for my delta loops and can vary the null between 20 and 30 db. This was operational for ground wave up to about 6 to 8 MHz. No resonant effects noted as far as the null was concerned. Using a non controllable resistor will vary the null due to temperature.

Enrique,

Looking at Dallas article, the Vactrol LED decoupling capacitor is 1uF. I would recommend a polyester type at say 50V. If this capacitor is placed at the Vactrol end then there is no need to use screened wires. Your should also consider providing static protection for the LDR side of the Vactrol. This can be done with 4 x 1N4148 wired in series plus another 4 diodes connected in the reverse direction. Both sets of diodes connected across the LDR side.

Hello Andy,

I am testing your FLG100LN, last Saturday I made a lopp, 8mx4m, with a 950 Ohms termination resistor, nulls were acceptable.
Sunday I made a smaller loop, 4x3m, with a 1050 Ohms terminatino resistor but nulls were poorer.

As I said before, I would like to build a 3x2m rotatable version feeded with the active interface. I think I could get good results.

Regarding Dallas article I do not understand the function of the 500 Ohms pot, is it a small PCB variable resistor ? Looking at the other scheme it only has a 1K pot.Is it necessary to play with two pots in Dallas scheme?

What is the value of the 1/10 capacitor, 10uf?
Sorry for these questions I am not very good at electronics.

Thanks for your help

Enrique,

I suspect that Dallas is using 500 Ohm pot to set the current so that the 1000 Ohm pot provides fine control of the Vactrol resistance. The article does suggest that is set for 270 Ohms. Maybe a 270 Ohm resistor is okay.

The 1/10 capacitor is 1uF at 10Volts. This capacitor is required because the Vactrol LED is non linear and can generate IMD which could be reradiated to the antenna by the control wires. I found this out the hard way when I used to manufacture the K9AY.

Dear Andy,

I will try with a fixed 270 Ohm resistor then.

Last question, I have an ALA100M mounted in a rotator, 2x2 m, works fine
but I need to use a tuner,grove mini-tuner tun-3, if not there is a lot of
intermodulations. I suspect that the loop is too large, manually this is not a problem
since i choose the swith range in the tuner but I have in mind to buy a SDR and when
recording there will be intermodulations since I want to record from 10 khz to 30Mhz.

Same happens with an ALA100LN, half delta loop 4x3 metres, feeded in the middle of the
vertical side. On SW the signal is excellent but on LW and MW signals are very attenuated
in some cases,on LW, there is no signal.
I have placed an attenuator at the input of the receiver but not significant result.
Again I suspect that I have to make smaller loops.

Thank you for your help.

Enrique,

If you are using Tuner between the ALA100M/ loop and the Rx, to reduce IMD, then the loop is overloading the receiver. So you may need to reduce the loop area.

The ALA100LN has a nominal input z of 60 Ohms and hence it is designed to the be used with a much larger aperture loop to provide good LW/MW reception. So I wouldn’t expect an IMD issue with your loop size, unless you have high power MW Tx close by. I would suggest that you don’t use any attenuation with this loop. Most users of the ALA100 and the LN version use a 20m circumference loop. The gain of both models is the same.

Hello Andy,

I have realized, with a variable attenuator, that the 100M gives 13db more than necessary. Maybe a 1,5 x 1,5 loop will be fine.

I have not a near MW transmitter,,, much worse I have a variable frequency controller. Noises and carriers come from the VFC,lift, and the most affected bands are LW and MW but I did not expect to affect in this way.

Thank you for your help again.

Having constructed resonant loop antennas for LW, MW and SW for many years, I have no knowledge of "fractal loops." A quick survey of the internet would suggest they add a third dimension, i.e., depth to a turn of the coil. Would this be a way of increasing effective height, while maintaining the same inductance (effective height being (2 x Pi x number of turns x area x cos angle) / wavelength)?

Hey, do you mean like a slinky antenna? Yeah, they work really well. Heh.

But I guess it's pretty much the same idea, sinusoidal in 3D. Fitting more conductor length into a shorter space.

The term "fractal antenna" has been rather misused over the last decade or so. Of course they can't be true fractals; the repeating shape has to stop repeating eventually. Some sooner than others.

All,
I have been in contact w/ Steve Nichols who reviewed this antenna when

it was called the "Crazy Daisy". He sent me the review so I guess I can
share it w/ the group (Moderator, please chime in if I am in error):

73,
Bob Cavanaugh - AG6YK

Catch: crazydaisy

Steve Nichols

RadCom

1400 words + pix

The Crazy Daisy magnetic loop antenna

Victor Borisov, GM0SDV is very keen on developing new antenna designs.
In 2011 Peter Dodd G3LDO reviewed his figure of eight magnetic loop
antenna constructed from 22mm tube. This turned out to be quite a
performer, coming within a fraction of a dB of the performance of a half
wave dipole during WSPR tests. The original review and antenna is
available from www.mixw.co.uk

Victor has now switched his attention to smaller antennas and visitors
to the Newark Hamfest in September may have seen his “Crazy Daisy”
magnetic loop antenna for HF on the RigExpert stand.

I asked Victor if I could take it away to test for RadCom and he was
more than happy for me to do so.

The Crazy Daisy has a unique petal-pattern main loop formed from
aluminium flat bar 3 mm thick, 36 mm wide. The overall diameter is about
87cm and it has eight zig-zag spokes or petals. It looks a little like a
child's “Crazy Daisy” toy that you connect a garden hose to, hence the name.

The loop is brought to resonance with a “butterfly” split stator
variable capacitor at the top which is in a weather-sealed enclosure.
The capacitor is connected to the loop via bolts secured by wing nuts.

The capacitor is turned by a small DC motor and reduction gear and
controlled by a small lightweight controller that is fed via a plug-in
12 V power supply, similar to a mobile phone charger. The box has a
“fast” and “slow” switch, which reduces the voltage to the motor and a
rocker switch for moving up and down the band.

There is no “up” or “down” button as such as the capacitor can rotate more than 360 degrees. This means that going “up” in frequency would depend upon where the capacitor position was to start with.

Tuning is done by listening for increased band noise as the capacitor is turned and then fine tuning to give the lowest SWR. The antenna is fed with a single-turn Faraday loop to which your coax is connected.

Victor says that the antenna can take up 400W although in testing I limited this to 100W.

The whole antenna is about three feet wide, relatively light and fits on a single pole, which I supported in the ground using a screw-in support obtained from Clas Ohlson.

The theory of how a magnetic loop works is quite well documented and I have used two different commercial varieties (MFJ and Capco/AAA) on and off for years so know pretty much what to expect.

When mounted vertically they offer a fan-shaped radiation pattern in a line with the loop with nulls off the side. At the horizon the radiation is vertically polarised, although overhead it is largely horizontal – just think about what you see when you look down on a magnetic loop and you can see why.

If built properly a magnetic, or more correctly small tuned loop (STL), can be very efficient, approaching dipole-like performance on 28 MHz (10m) and a few dB down on the lower HF bands. I say “built properly” as you have to ensure that losses are kept to a minimum by using good quality components with very low loss connections, such as welded or brazed. A few milli-Ohms of loss can drastically affect the performance of a loop and many proponents of the loop art advocate using vacuum variable or split stator capacitors to reduce losses.

And if you think that everything is known about the STL and its performance think again. Rich Fusinski K8NDS is currently experimenting with helically-loaded magnetic loops that use copper flashing rather than tubing. When fitted with a vacuum variable capacitor and fed with a gamma match he is getting good reports and can even run 1kW into them without problems.

There is a debate about whether K8NDS's antenna is more efficient than a conventional loop made out of copper tubing, but it is good to see experimentation going on.

Anyway, back to the “Crazy Daisy”, on test it was found to tune from 12.4 MHz to 29.5 MHz. The positioning of the Faraday loop was found to be critical, but I was able to get the SWR down to around 1:1.2 or less on some frequencies and less than 1.8:1 across the whole frequency range.

As you would expect the bandwidth once tuned was narrow – about 50 kHz between 3:1 SWR points on 20m (14 MHz), 84 kHz on 15m (21 MHz) and 125 kHz on 10m (28 MHz).

On receive the first thing that struck me was just how quiet the antenna is. Band noise was minimal, which meant that weak signals were received loud and clear. Tuning around it was clear that the loop was receiving just about everything my main antennas could hear. Usually signals were down a little when compared with my dipoles, but the lower noise floor meant that the overall signal to noise ratio was about the same.

This suggests that the antenna would be an excellent choice for a short wave listener who doesn't have the space for a full-size antenna. One antenna could be used to cover everything from 12.4 to 29.5 MHz, including amateur, shortwave broadcast, aeronautical and anything else in the spectrum. If you live in a flat with no access to a garden the “Crazy Daisy” could be located on a balcony and enable you to play radio.

So how well does the “Crazy Daisy” work? I decided to test the antenna using WSPR (Weak Signal Propagation Reporter). I used 5W and transmitted for two, two-minute periods with the loop (tuned to the appropriate WSPR frequency). I then switched antennas and transmitted again.

By going to _www.wsprnet.org <http://www.wsprnet.org/>_ I was then able to see where my signals had been received and what signal strength. I then took only the reports where the signals had been received from both antennas and calculated a mean (average) signal strength.

The results showed that on 20m (14 MHz) the Crazy Daisy mounted with the base just four feet off the ground was down about 9.4-9.7dB on a half wave dipole mounted at 25 feet.

To give the full picture, signals from the dipole were received by more reporting stations than the “Crazy Daisy”, which is to be expected given the performance outlined above.

Similar results were obtained on 18 MHz (17m) and 21 MHz (15m), were conditions were not too good at the time of the tests.

On 10m the antenna performed slightly better (as you would expect, where its physical size is less small compared with the wavelength in use). Here it was around 6dB down on a 28 MHz dipole at 25 feet.

The different radiation patterns and vagaries of the ionosphere meant that some signals were similar in strength and some were worse.

This led me to believe that for optimum efficiency it would make sense to mount the “Crazy Daisy” on a rotator so that you can align it with the area of the world you wish to work.

Once the tests were over it was time to think about the results and why the antenna performs the way it does. Current wisdom is that one of the critical factors of a magnetic loop antenna is the area enclosed by the loop. For example, for a circular loop of radius 40 cm the enclosed area is Pi x radius squared = 0.5m^2 .

Now, although the overall width of the “Crazy Daisy” is about 87cm, its design means that it covers roughly the same area as a circle of

approximate radius 0.3m, giving a total enclosed area of about 0.28m^2 .

Feeding these figures into the late Reg Edwards G4FGQ's loop calculating program (RJELoop1.exe) suggests that its performance might be about 3dB down on a circular loop of about 80cm diameter.

Either way, I think Victor GM0SDV should be congratulated on experimenting with different loop designs and the antenna enables a ham with little space to get on the air. The fact that the loop received and transmitted signals to the USA, Canada, Israel and Reunion Island and took about 30 minutes to erect says it all.

Victor says that he builds the antennas for fun and ploughs the money that he makes from selling them back into research and design – he is currently interested in fractal antennas, which he feels could offer a lot of performance for their size.

The Crazy Daisy is available from KMK UK Limited (e-mail: mixw@...

or web: _www.mixw.co.uk <http://www.mixw.co.uk/>_) for £200 + P&P. Our thanks to Victor for lending the antenna to us for review.

10774. Drake AL-4 Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-09-26 23:50:58 UTC
From: hmholden69@...
Topic: 10774 Message: 10774

I want to build this antenna, Looks like it is made of RG-174 coax. Does anyone have a schematic that shows how the coax is wired to the male jack that plugs into the radio?

Hi,

Appearantly there is a space in the shield like most loop antennas at the top. I've seen two AL-4 photo's but not an actual one yet and there is a light colored section, probably plastic tubing, in the center of the top section. A 0.25 to 0.5in space should be enough. Looks like the coax is just threaded through holes/loops on the ends of the arms/spokes of the antenna.

I'll attach a photo of one but the group probably does not allow photo's. In case of that I will also send the photo direct to you.

The radio side shows the tip of the plug is the "hot" side and the ring is the ground. Since there are only two connections and no " live" voltages/current, I would not think it would matter which is which. Of course you would want to "jump" the ends of the coax shield at the bottom.

According to the manual the antenna was only good for 150-1600 kHz.

Good DX!

The light color space at the top of the loop probably means its a break in the shield . I know that on the SPR4 and probably the SW4 that the loop goes to a jack that connects to a loop amplifier. Its Q1 on the SPR4. So it looks like they used a piece of RG-174 to build a shielded loop. Wish I had a schematic to look at to see if they were making a Faraday type config.

Hello all,

I have had one but it was sold wth the reciever some years ago. The coax was about RG174 size, there was no tuning cap of any sort - it was broadband - and only worked in the mw range of the reciever. I remember from the circuit diagramme I had that it fed into a grounded base amplifier using a single transistor.

Cannot say if there was a break in the coax shield making it a shielded loop or whether inner and outer were tied together just basically making a single conductor loop. Performance-wise it worked OK given it was used indoors.

Sorry but that is all the info I can recall.

Regards, John

I, too, had the SPR-4/AL-4 combo... and my name is John as well! I sold it probably twenty-five plus years ago. I recall it being unbalanced - and not much for symmetrical nulls. Additionally, it's 1/4" phone plug end fitted through a hole, revealed by removing a cover/plug in the top, down into the chassis top mounted phone jack. It was grounded by the ring/sleeve, making it noisy to bump, much less to rotate. With the SPR-4's 'slow' stock AGC, that was aggravating. While I logged many LW aero beacons on my LW, that AL-4 was of little use at my receiving station's location - below grade and under fluorescent lights (I never found the NB-5 noise blanker for the SPR-4.

I always wanted to try my four foot box loop plugged into the SPR-4's common base loop amp - but never did, other than via the antenna input, which I always wanted to change from the dinky RCA phono jack to a BNC. I still miss the SPR-4, it's aggravating quirks having been lost in my memory some time back. I still check evil-bay for a 'good' one...

If you make a 'similar' loop of RG-174, don't terminate it in a phone plug. Use something better for a bearing - on a large base - with 180 degree rotation limits and provide a decent connector (BNC), too.... essentially, hard-wiring the lead-in.

John

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

WIRE "Flex-Weave" Antenna Wire
"Flex-Weave" is a hybrid aerial wire that consists of 168 strands of woven #36 solid copper wires that provide high strength and extreme flexibility. The most popular version of "Flex-Weave" is the 'equivalent' of #14 AWG wire size. It can be 'used' for unsupported spans up to 200 ft (100-150 ft in areas with high ice and wind loading).

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-10-01 13:30:11 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10782

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Hi

Does anybody have any knowledge of this antenna.

http://www.aorusa.com/antennas/la800.html http://www.aorusa.com/antennas/la800.html

I wonder how it "tunes "
It's expensive.

Regards to all

Stephen

They say it is tuned by relays. I expect they are selecting a capacitor using relays for the band and then use a varactor to tune the frequency.

Interesting

As I understand it, the loop is not tuned in the convention sense by varying the electrical length
but by the use of filters.

This is still going to give a wide recieve spectrum, by no means a high Q

Regards

Stephen

Hello,

there's a MT article on it here:
http://www.monitoringtimes.com/0613firstlookaorla400.pdf

I found odd the term "aligned/unaligned" range. I wonder if it means if it refers to the radiation pattern (where the antenna shows deep nulls) or the tuning range.

My guess: unaligned range means the antenna element (alu loop) is only connected to the preamp terminals. Aligned range uses a switched inductors plus a varactor for tuning.

Loop Antenna News and Information ForumThat’s my understanding: the “unaligned range” is outside the manual tuning range
of the antenna, but where it still offers useful sensitivity.
When I read posts here about its “high price”, I expected a price in the 4 digits.
(Well, as I write this, I realize that with the impedance transformer and coax isolater add-ons, the price will get into 4 digits....) But it occurred to me that many, if not most people looking at such antennas already have that much or more invested in their receiving equipment.

Topic: 10794 Message: 10795

If your box loop is set up for 75Ohms then soldering one side of the feedline to the center conductor of a PL-239 and the other to the shell should be close enough for Gummint work. With 3' of feeder any mismatch is going to be negligible.

I use a remote tuned loop with an RG6 (75Ohm) feeder about 45' long connected to a PL-239 into my R-71A and it works just fine.

Hi,
Is this for transmitting or receiving? Matching is much more important when you are transmitting. A mismatch between 50 ohms to 75 ohms is only 1.5:1. I would accept that even if I was transmitting a high power signal. If you are just receiving the difference in received power should not even be detectable. I second the opinion to ignore it. I would recommend that you cobble up some sort of connector to match your SO-239. I would suggest attaching something simple to the feedline such as an RCA phono plug and use a conversion jack to attach it to your radio connector. Just make sure that however you attach it you provide sufficient strain relief on the feedline and you should be good to go.

73,
Bob Cavanaugh - AG6YK

From: dx11
Topic: 10794 Message: 10797

How the feed line is connected to the FRG7 is the minor problem, the main question in this case is how the feed line is connected to the tuned loop.

The feed line impedance of 75 Ohms needs to be connected to a loop impedance with about the same value. How is that achieved?

Has it got a Faraday loop, a Gamma match or something else?

Please elaborate on that, than we can give you an answer that will help you.

If your 3ft tuned loop has a separate winding for the balanced pickup and that is connected to the Zip cord, simply connect one of them to the inner red 'BC' connector and the other to the adjacent black 'E'. Also, a proper ground, or 'Earth' connection, should be made to the radio. A dedicated ground rod is sufficient. I found the back panel pictured in Universal Radio's discontinued listing for the FRG-7 and it's schematic elsewhere on the web. Interestingly, the red 'BC' connector goes via a separate selected attenuator resistor pad directly to the MW preselector coil, while the other red connector and the parallel connected SO-239 jack (PL-259 receptacle) are only used on SW. A short jumper run between the two red connectors will allow the SO-239 jack to be used on MW, if you want. The detrimental effect of unbalancing the balanced feed may present as a decrease in the null symmetry on local groundwave signals - hardly a bother! BTW, there is a 22pF cap between the two red terminals internally - presumably to offer a 'Hi Z' antenna input (Universal said 500/50 Ohms for input Z). If you were to plug the loop into the SO-239 without the aforementioned jumper it would be like placing a 7 kilOhm resistance in series. I'd connect the Zip wire antenna between the 'BC' and 'E' connectors.

If your tuned box loop doesn't pick up much signal AND the tuning capacitor seems ineffectual, your Zip cord is likely connected across the parallel connected coil and tuning capacitor - and that is wrong! Wind a single turn pickup loop just inside the other loop and connect it to the Zip cord to the receiver.

Years ago, in my more active days, I went through a myriad of receivers - including an FRG-7 - I still have fond memories of using it!

John

I am curious about the purpose of a ground when using a loop antenna. I know a ground is important when using a long wire as the ground is part of the antenna. But a loop doesn't require a ground connection to function properly does it?

Heck, I've always heard that ground loops are not good... ;)

If anyone is looking for a very nice air tuned loop antenna I will be attending the Stone Mountain Hamfest North of Atlanta, GA on November 1 and will only be there on Saterday. I can be found in the Boneyard flea market area. http://www.stonemountainhamfest.com/

Pictured below are some of the loops that will be for sale. I have sold all of my FSL antennas, but may build some later to use up all of my ferrite bars and variable capacitors.

If the antenna is balanced and you want to maintain that balance (which can be important for a loop antenna), then the best or "right" way to connect it to an unbalanced receiver input is with a balun. It is essentially a transformer, or functions similarly to one. Some baluns also transform the impedance, but not necessarily. There are many plans online for building many kinds of baluns.

Regarding grounds, I am of the opinion that they generally are not needed (except for safety) and often are better off avoided. However, for a receive-only situation, it can be helpful to have a ground available, and try it, just to see if reception is better with it or without it. For a loop antenna, grounding it (making the loop unbalanced) might increase the received signal strength because now the feedline and the ground wire become part of the antenna, not just the loop itself. That can be good and bad. It tends to destroy the loop antenna's nice figure-8 pattern with deep nulls, and make the antenna more responsive to electrical noise that it would have rejected if it was nicely balanced. But try it both ways.

Ground loops can be bad, but not always. Often they are unavoidable, especially at RF.

Surplus to my needs, have a 3-30pF, 15/9 kVp Jennings variable tuning vacuum capacitor (P/N CADD-30-0515). Has 1/4" shaft, with end to turns of 15. Picture attached.

Before posting to other sites (e.g. desirable for high power amplifiers), offering here first for transmitting use in a small loop antenna (e.g. given typical dimensions capable of tuning a 20 - 30 Mhz small transmitting loop.

Asking $60 + shipping

Also have a couple of 215pF air variable transmitting capacitors @ 4500 volts for $30 each, plus shipping.

Please reply off list to topossibilities'at'yahoo.com

Here is a place you can buy yourself a TERK AM loop antenna, even some other stuff that is kind of off topic to talk about. 73
http://www.amazon.com/exec/obidos/ASIN/B000069EUW/qid=1075080062/sr=2-1/ref=sr_2_1/102-8712984-4397719

WL1030 by the late Maartenhagg. Plans placed on this website by his friends in his honor.
http://wl1030.com/content/

C Crane Company
They sell the Justice AM Loop Antenna, Select A Tenna, Terk AM 1000
http://www.ccrane.com

Kiwa Electronics
Kwia makes the best products for you and your radio equipment, and also improves things that needed improvement a long time ago.
http://www.kiwa.com

Stormwise Ferrite Rods
Get some huge ferrite rods and a converter to go along with its, heck it even comes with project book.
http://www.stormwise.com

Universal Radio Company
They sell all sorts of loops big and small for LW/MW/SW and VLF also 10 kHz to 15 MHz
http://www.rffun.com

ALA-1530
Find the best UK LF/MF antenna here.
http://www.wellbrook.uk.com/

AOR
This is the site that sells the AOR loop
http://www.aorja.com/ant-e.html

Kiwa Electronics
The maker of the air core loop antenna and other useful items that you may want on your wish list.
http://www.kiwa.com

LF Engineering Company
A group of engineers, who make products for VLF/LF listening even ELF loops!
http://www.lfengineering.com

Select A Tenna by Intensitronics Corp
The maker of the select A tenna, a great AM loop antenna that is a little bigger than the terk
discontinued

Terk Technolegies
The maker of the best sold AM and I use also called the AM-1000 AM loop antenna, there is also technical information on how it works.
http://www.terk.com

Torus Tuner Loop Company
A very specially made loop that is almost as big as a hula hoop
discontinued

GRAHN (Germany) Specialized Loop Antennas for MW and SW Reception Contributed by radiohighfreq
Grahn offers both Ferrite Rod Antennas and Shielded Loop Antennas. Translated from the Gremany Language Webpages here is the "Grahn Specialized Loop Antennas for MW and SW Reception" ULR Address: http://www.grahn-spezialantennen.de/

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10804. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-11-01 14:02:50 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10804

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

From: Andrew Ikin
Topic: 10809 Message: 10810

Hello Piotr,

Thanks for the interesting demonstration.

What size loops were you using with the ALA100LNs? Also what was the antenna separation and orientation?
I assume that the adaptive polarisation is a cleaver way of optimising the phase difference between the two channel SDR? “most impressive”

Andrew,

the circumference of the loops is aprroximately 12 meters. Distance between them about 9 meters.
The setup is neither broadside nor endfire, just a random temporary location close to a building.

The pattern is completely unpredictable because of proximity o metal objects. But the smart software did it job and found a null to cancel the noise.

Regards

Piotr, SP2BPD

I know it's a 7 year old post but just in case mhatlau is still on the list... and if one of you knows how to contact him please forward this to him - thanks.
I am writing a book about improvised radios built by servicemen in the field, mostly during WWII but also before and after. The stories of the soldiers, sailors and marines and their experiences are all tied to the thread of the “foxhole” radios they built. I’ve interviewed many veterans and their families and am past the research stage but I still occasionally check old sources in case I missed anything. I was very happy to stumble on an old news group post of yours that mentions a foxhole radio constructed by your uncle. It’s one of the few I’ve run across built in the Pacific (most were built in Italy) so naturally I’d love to hear more of the story. Do you happen to have a picture of it? Not many exist of the original sets, and I only know of one – possibly two – that were brought back. - brian bcarusella at gmail dot com

Hello

For those who may be interested, I have now had the chance to try this aerial.

The good news is that it is well made, the bad news is that is dreadful.
I compared it against the 7 other loop antennas I have, of which 4 are commercial, and it was the worst of the lot by a long long way.

I cannot understand AOR producing this expensive and very poorly performing antenna, perhaps I had a duff unit.

The Wellbrook or Pixel are much better at 1/3rd the cost of the AOR (UK prices)

I cannot think why anybody would want to buy the AOR, but be aware that the control cable is only 33ft in length, this means it is unlikely you would be able to mount the aerial far enough away from the electrical field of noise created by your house / shack.

In my case I have to mount all loops a minimum of 50ft from the house which meant for my tests I had to shutdown 90% + of the house electrics to create a similar environment.

This post is for general information only, AOR have done good things over the years but this aerial is not one of them.

Regards to all

Stephen

Stephen,

Can you expand on what is wrong with the AOR loop i.e is it low sensitivity, poor local noise rejection or high IMD.
Or is it pain to keep tuning it!!

Hello Andrew

When I first installed the AOR the noise floor was very high around -40 dBM, I put this down to the fact I had the aerial mounted close to the house because of the "short" control cable. When I shut down most of the house electrics the noise dropped to around -83 dBM. My standard 1530 loop mounted 55 ft from the house has -98 dBM in normal operation. The 1010 loop will actually be better than that, but the 1530 is a better comparision for the AOR.

My radio with no antenna connected shows -130 dBM with all the house electrics on.

I then mounted a second 1530 alongside the AOR and had readings of -83 dBM (AOR) & -90 dBM (Welbrook) I did use a number of ferrite choke cores on the AOR but they made no difference.

The tuning of the AOR is very very sharp, which is fine IF you know the frequency you want if not it's a real pain. The preset frequency ranges given by the control box are ok, with an option to use the antenna in broadband mode which I found to be useless. I was told that the AOR uses a series of band pass / cut off filters to achive it's "tuning" , if that is correct then they work reasonably well.

Because of the very sharp tunning I did not find IMD to be an issue, but then if the antenna is deaf IMD is automatically less of an issue.

Remember that the control cable supplies power to the antenna and with no power the antenna will not function at all, I do not complain about that, but I was unable to discover if a longer control cable is available or the wiring configuration of the cable (supplied by Buffalo). So a longer control cable might be a challenge, unless you cut and splice.

Compared to the 1530 the AOR was seriously deaf, so bad was it I thought I had an installation problem and double checked my work.

I have a couple of very experienced ham radio enthusiasts near me, who know more about aerials than I ever will and I invited them over to see if my findings were correct. They were as surprised at just how bad the AOR was, I say again perhaps I had a bad unit.

Given that the AOR is deaf right out of the box, then having to mount the aerial within the electrical field of the house because of the short control cable makes the aerial unusable. I must repeat again that perhaps I had a bad unit, I do hope I did because this is not the sort of product I would expect from AOR let alone for the very high UK price.

This is just my personal experience of the AOR.

Kind regards

Stephen

Thanks Stephen,

I would expect that a tuned loop would provide at least a 10dB improvement in s/n compared to any Broadband loop; assuming that both antennas are used in quiet RF environment.
If you suspect the AOR is bad; is it possible to return it for a replacement?

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10823. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-12-01 15:11:59 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10823

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Steve Greenfield

10824. Pixel Pro-1a rotator suggestions?

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-12-03 14:11:46 UTC
From: JRTOW3RD@...
Topic: 10824 Message: 10824

I mounted my previously outdoor mounted Pro-1a and it's 5 ft mast into a CM tripod base and sat it in the floored walkup attic of the garden home I moved to 7/13. It's a bit of a trip to go for the trek to the other end of the hose, thru a door, upstairs, thru another door, and back to roughly over the office where I have my 'shack' - then turn the antenna - and return. I couldn't tell which direction the null is now, either! I need a rotator! I am considering the RS 15-1245 rotator ($60 less $10 'coupon'...), as it looks to have a rotation 'indicator' of some sort. I imagine it's not inherently synchronized - but should last as the temperature extremes of my attic are all it will have to contend with... hopefully! Suggestions/opinins/use-reports would certainly be appreciated! Thank you.

John

Hi John;

I am using an AR-303 rotator with a small resonant loop, and have had this mounted outdoors for about 3 years now. This appears to be identical to the RS unit. I have had no problems with the rotator head itself, and it has worked without problems here in Chicago in temps down to -20F. I do not use it for DFing or signal nulling, but tweak it occasionally to depress local noise as heard on the loop.

The control itself has its issues, and I have had to open it a couple of times to find and remove pieces of broken plastic which jammed it up. This appears to be a common problem, but none of the problems I have had have been game enders.

For $50 this is a good deal and should work fine, especially for an indoor siting.

The detrimental effect on efficiency of helical winding of a small loop has finally been verified in practice by K4HKX with experimental data measured using the Reverse Beacon Network and carefully controlling for environmental parameters. The result: helical winding introduces loss, about 1-2 dB with K4HKX's loop, compared to a non-helically-wound loop of equivalent enclosed area. W8JI already pointed this out more than three years ago when the helically-wound loop was first proposed. Quote by W8JI: "Regretfully, all helcially winding the small loop does is increase inductance and loss resistance. It is of no benefit at all for radiation." (Reference: http://www.eham.net/articles/26572 http://www.eham.net/articles/26572)

The measured objective data showing this conclusion can be seen here: http://qrz.com/db/k4hkx http://qrz.com/db/k4hkx (see "Section 3: Magloop Comparisons vs My Reference 40M Dipole:" and "Section 9: Helically Wound Magloop".

Simply winding the strap non-helically around the support frame would improve efficiency (see for example K4HKX's aluminum strap loop) by reducing the current path length and the loss resistance.

Best regards,

It would be very easy to build a loop and put in lumped element
inductors to experimentally verify that magic happens or doesn't happen.
But consider this thought experiment. If the loop radiation
resistance is only 0.013 ohms, any coils you insert with more than a few
dozen ohms of reactance add significant losses relative to 0.013 ohms.
But a few dozen ohms of reactance has negligible effect on anything. A
helically wound strap is not a free lunch. The total conductor path is

longer and narrower, hence increasing losses.

It has been experimentally verified countless times that helically loaded verticals have no special properties compared to conventional loading coils. Why should it be different with loops?

>
> Yet to be explained as well is the phenom where Ae > physical size as it

What is it that hasn't been explained? Lots of antennas have Ae > physical size. That doesn't mean that helically wound loops have additional Ae. Where physical size comes into play is that you cannot simultaneously have small physical size and high efficiency without extremely narrow bandwidth and limited power handling due to the necessarily high loaded Q. The proof of this is independent of how the antenna is constructed. The article originally cited makes no mention of bandwidth.

Let's cut to the chase, per the author:

The helical loop (#3) is the least efficient, also as expected due to the extra length copper conductor, increased skin effect and current crowding losses.

BTW, that was 12.5 mil copper tape he used, and not all quote "copper" unquote alloys posses the same conductivity.

Overall, I'm surprised the correlation was within 1.5 dB given differences; I would have used 1) a larger diameter form and 2) greater spacing between turns and 3) constructed a reference loop using the same copper tape.

BTW, if you start letting W8JI write your physics handbooks you will set 'science' back about 100 years ... he's right when it comes to bread and butter mainstream 'hammy' issues but runs out gas on the fringes (IOW he is not a physicist.)

10830. Quick and easy AM broadcast antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-12-08 16:32:54 UTC
From: Gordon Quickstad
Topic: 10830 Message: 10830

THE STORY:
I bought a new Sharp compact stereo and the AM reception is worse than horrible with the supplied 8-loops-of-wire-on-a-plastic-form "AM antenna." My 20 year old Aiwa that I replaced had the same exact plastic antenna but with 6 loops of wire.

I went to Goodwill and bought a $3.99 clock radio thinking I'd take the ferrite rod antenna out, wrap some wire around it, and voila, plug it in as an external antenna. While looking closely inside, I see that the ferrite rod is actually connected to the tuning capacitor and is part of a resonate circuit so I put the the radio back together, checked it for working again, and I'll use the in-store credit to buy a shirt.

GETTING CLOSE TO THE QUESTION:
Last night I got on Ebay and found 200' of 10/46 Litz wire for $7 and ordered it. This hair-brained idea is to wind the small Litz wire on the stock wire - loop form and get better reception (more turns is better, right?)

THE QUESTION:
Can I use 200' of small Litz wire, when it arrives, in place of the supplied antenna of the short 8 wire loop and get better AM reception? I really don't want to have an antenna that I have to tune with an external capacitor. Of course I'm OK with spinning it around to adjust for maximum signal.

Thanks in advance.

How do you know the antenna is at fault? What specifically is the problem with reception? "Modern" AM tuners are of the "tuner on a chip" variety, and the newer designs eschoo passives so the whole tuner is indeed on the chip. This results in inferior performance to older designs.

I think you answered your own question. The 20 year old Aiwa has the same antenna (except for the unimportant detail of the number of turns) and works great.

Both the historical GE Superradio's and the current ones use ferrite rod antennas. But the electronics in the current ones are junk.

If your only problem with the Sharp is insufficient sensitivity, simply replace the supplied loop with a larger one with fewer turns to maintain the inductance. Doubling the size will magically give you 6 dB more signal.

Thanks for the help.

To expand a little, the problem is poor signal to noise ratio on (probably) all stations. Other old discrete electronics portable radios that I own in the same location pull in the stations clearly with their ferrite antennae. I bought the Litz wire because I'm thinking that using low-loss Litz wire on the stock antenna form, and lots of turns, will help. I didn't know that using a physically larger loop would give 6db in itself. Yes, you're right, both the AM and FM electronics on the radio are in a very small shielded enclosure right where the antennas plug into in back and it's about "chip" sized (I saw it when I had to fix the CD changer on the newly purchased system because A. I'm mechanically inclined and B. don't like waiting for repairs, so I took the risk and broke the warranty and went inside with success but no future warranty).

Shouldn't just using more turns on the stock form intercept more signal and improve the SNR? And how about more turns AND also changing to a larger antenna form to wind turns on? Since it's a shelf stereo, I'm size limited on space for spinning the antenna around to the best reception.

There are some neat talk programs on AM because air time is so cheap so I do like to break away from the typical FM fare but can't stand just 50% signal with 50% static noise which I currently have.

Increasing the number of turns increases signal VOLTAGE
but also increases inductance. If the radio electronics
are resonating out the inductance, you don't want to mess
with the value of inductance. (If the radio electronics
are NOT resonating out the inductance, no wonder you have
such poor sensitivity). If you double the diameter, but
use 70.7% as many turns the inductance will remain the
same. You can also make the loop taller but not wider.
This will still give you more pickup area but will not
exceed the space behind the radio.

I had the same problem with a $150 Sony stereo. The AM reception is really terrible. I live east of Los Angeles and the AM band is chock full of stations but the stereo will hardly pick up any except the 50000 watters. Also it acts like there is no AGC. High power stations like KFI come in only fair and weaker ones like 10000 watts are too poor and noisy to listen to. The volume must be turned up high to hear them like the 50 kW stations. Then you have to remember to back down the volume before changing stations.

Anyway I "solved" it with an external outside active antenna. But I was still not happy. The no AGC problem bugged me so I now use a $100 Drake PRN 1000 100 kHz - 30 mHz SW AM only receiver with the active antenna and feed the audio to the "portable" input.

You can use the extra little loop to couple another antenna with some wire connected to it to your rx by placing the two loops close together and changing the orientation for best reception. Maybe that will help without spending a bunch of $$$.

One more thing that was implied but not stated:The radio will pick up most efficiently at resonance, which requires both the inductance and the capacitance of the final (tuned circuit+antenna system) to be matched {Fr = 1/(2*pi*sqrt(L*C))}. If you increase the inductance of the antenna beyond the range of the variable capacitor (either external or internal varactor) you don't buy yourself anything except worse performance (the loop will act as a pre-selector and mute the signal of interest). Make sure you keep the inductance of the antenna system roughly the same, which means as stated earlier in this thread increasing the area enclosed by the loop if you increase the number of turns. Inductance increases roughly by the square of the number of turns so you need to increase the area accordingly (as stated earlier in the thread).

Assuming this is a typical digital AM receiver, the original ferrite "loop" antenna is untuned and feeds an FET RF amplifier as a broadband antenna. That's why it's not particularly sensitive. Good results can be obtained winding about 5 turns of hook-up wire around the existing coil (no direct connection) to serve as an inductively-coupled pickup. The ends of the added pick-up coil can then be used as the connection point for a simple dipole or another loop. A long wire can be connected to one lead of the added pick-up coil, but the remaining lead should be grounded.

Regards,

Dexter

I would love to try my 3 Ft.Box Loop antenna with a car radio, but not sure how to interface the two. I have been told that the normal cable from the car antenna to the radio is a special low capacity type. Any ideas on how to hook up a loop to a car radio in the shack? I have an especially good car radio that I would like to MW DX with using my box loop.

The whip antenna acts as if it is a low value capacitor, say 10 pF or
so. The capacitance of the cable would form a capacitor divider and
most of the signal from the antenna would be lost.

A box loop with either an amplifier or a low impedance coupling loop can
drive normal coax without excess signal loss.

Car antenna plugs are available on ebay.
<http://www.ebay.com/itm/5pcs-Car-Radio-Auto-Motorola-Type-Male-Antenna-Plug-Connector-STR
AIGHT-/151491148914?pt=US_Radio_Antennas&hash=item2345937c72>
These are sometimes called Motorola connectors
https://en.wikipedia.org/wiki/Motorola_connector

A premade radio antenna to BNC cable along with an adapter from BNC to
the connector type on the loop, along with a BNC extension might be the
easiest approach.

The radios I grew up with, and a lot of aftermarket radios, use a Motorola connector. Newer car radios, especially the multi-function radios that are now common, use what is called a FAKRA connector. These are smaller coaxial connectors with locking tabs and color coding for the application (AM/FM, satellite, gps, etc). They are also 50 ohm impedance. You can find FAKRA-to-Motorola pigtails on Ebay and at

http://www.installer.com/main.php?page=antenna-parts

Installer.com also listed amplified whip antennas at that link. They'd be a lot easier to install than a loop. You could also roll your own, such as the PA0RDT mini-whip.

I got my AlexLoop Walkman antenna in the mail today (FYI $339.95 On Sale HRO but GigaParts matched price). I am absolutely BLOWN AWAY at how well this small 36" loop woks. In less than a few minutes I was working stateside stations on 20M. My first contact was WIAW / Portable 4 in Georgia with 5/9 report. As well as several other stations. I am blown away at how well this small antenna performs!!!! I have a MicroTune AlphaLoop on the way as well to compare the two. This is my first loop antenna experience and I am impressed!!!! Your question is rather vague, but perhaps the following document may be of help.

http://www.ece.msstate.edu/~donohoe/ece4990notes5.pdf
http://www.ece.msstate.edu/~donohoe/ece4990notes5.pdf

Quote from page 6 of that document: "The fields radiated by an electrically small loop antenna can be increased by adding multiple turns. For the far fields, the added height of multiple turns is immaterial and the resulting far fields for a multiple turn loop antenna can be found by simply multiplying the single turn loop antenna fields by the number of turns N."

The radiation increase isn't free, however. You need to think about the loss you are adding as well by introducing the extra turns. The total conductor length is increased, and the current distribution in the multi-turn structure will not be uniform due to proximity effect (which increases ohmic loss).

I think a carefully-engineered multi-turn loop could be more efficient than a single-turn loop for certain frequencies.

At best they can be similar. The intra-winding (between turns) capacitance will cause the parallel resonance to be lower. The turns should be spaced at least two conductor diameters apart. I described this in my 2-part series on loop antennas in QEX many years ago.

Ribbon cable is a very bad idea.

10847. Ferrite Sleeve Loops Antennas (FSL) For Sale

Yahoo group: loopantennas (2013 — 2017)
Date: 2014-12-25 16:37:50 UTC
From: everettsharp@...
Topic: 10847 Message: 10847

If anyone is interested, I am in the process of building two 7.5" diameter X 7.5" long Ferrite Sleeve Loop Antennas (FSL). In the past I have done many experiments with this size FSL, and there is an article posted on this sight covering those experiments.

I will be selling both of them and will either build them as single band, or dual band. With the single band units I can build them for LW, or MW coverage. With the dual band units they will cover both LW and MW bands. Based on my past experiments I know that they will perform equal to, or better than a 4' box loop. My method of building is using ferrite bars rather than rods and based on my experiments, I can not tell any difference in performance between the two methods. With the bars they are much lighter in weight and allow for a much nicer looking build.

Both FSLs will have Red Oak end pieces and will be mounted on a Lazy Susan with Red Oak top and bottom. The variable capacitors that I will use are the very small Russian high Q units, with a 3:1 turn ratio. The front panels will have nice looking graphics.

The prices for the FSLs will be $400 for MW band coverage, $435 for LW coverage and $475 for dual band coverage, plus shipping cost. These will be built first class, no junk. At this point I have most of the mechanical work completed and the ferrite bars have been epoxied to the substrates and covered with fiberglass and are ready to be wound.

These maybe the last that I build, although I still have materials to build more.

If anyone is interested in one of these please contact me off list at everettsharp A O L and I will configure them to your specification.

Very good! Good to see the loop is performing for you!

Tonight, as last night, I'm getting WSPR* 'spots' on a loop long-path to VK-land on 40 meters at 4:30 PM CST ... the loop here is a Quarter-wavelength, 32 ft circumference, 8 ft per side tuned loop about 12 ft above ground out in the back yard.

Proof, again, that loop can and do work!

A thought or two to consider: If you make a small 1-turn loop that is 50% efficient, then half the power you feed into it gets turned into RF that radiates. If you make a small 2-turn loop and manage to keep the efficiency at 50%, the best it can do is radiate the same.

In order to get a better radiator, either the efficiency must go up (less losses), or the antenna can be made more directional to concentrate some of that energy in a particular direction. I don't think you can change the directionality of an electrically small loop by using the same basic coil form. Any electrically small round loop in air has pretty much the same directionality to it.

So the thing you need to concentrate on, is cutting the I*R losses.

Connecting the turns in parallel, rather than series, may help with that.

The different number of turns can affect the impedance seen by whatever drives the antenna, so it might affect your ability to match the antenna and get power into it.

A large loop antenna (i.e., circumference comparable to a half wavelength or more) plays by different rules than a small loop. In a small loop where the total wire length is short, the current in each turn is the same, so their effects complement one another. In a large loop, the currents could be out-of-phase between one turn and the next turn, resulting in rather different results (partial cancellation?).

Regards,
Andy

Yes, but what makes you believe the efficiency will be the same? Adding loops raises the impedance which means the same power will have a higher voltage and lower current after matching. This in turn means the I2R losses will be lower in spite of the higher resistance. Here is an example.

A 2 turn loop has four times the impedance so the current will be a quarter. The resistance will double. The resulting I2R losses will be (1/4)^2*2 or 1/8 the losses compared to a single turn loop if the same conductor is used.

Of course if you are using a single turn loop for transmitting it is likely to be something substantial such as copper pipe. That makes it hard to build with multiple turns. But I don't think paralleling turns would do what you expect. Then there are the losses in impedance matching if needed.

Rick,

I assume you want to make your comparison for the situation where the power remains the same. In that case a four times higher impedance results in a voltage that is twice as high and a current that is halved. So the resulting power loss is 1/2 instead of 1/8. Or is it me who’s wrong?
>>A 2 turn loop has four times the impedance so the current will be a quarter. The resistance will double. The resulting I2R losses will be (1/4)^2*2 or 1/8 the losses compared to a single turn loop if the same conductor is used.<<

But the meaning of your statement does not change.

Yes, you are absolutely right. I'm down with a cold and there is no room left for doing things in my head, lol. As you say, for constant power to the antenna the voltage will double and the current will halve. Using I2R the resistive power loss will be cut in half, not 1/8 as I wrote before.

I don't know if it is common to link antenna efficiency to Q, but in this case the equations seem to be the same. It is the ratio of the inductive reactance to the resistance, as long as the reactance dominates.

Hi Chris,

Along the same lines, I have an MFJ-936B loop tuner with all 4 pre-cut 10 Gage wires. If the 28' 40M wire is spread out properly it apparently gets 30% efficiency or so. I have the cross-t frame which is supposed to only handle up to the 13' 20-30M wire, however, I have wound the 28' wire on the frame in a spiral, using all the clips to keep the wire 2"-3" away from itself. The spiral is essentially in 3 progressively smaller loops (5' down to maybe 2'). It seems to work well and I have had no arcing, at least to 50 watts which is the max I use anyway. I have done Pactor/Winmor at 5 watts up to around 800 miles in the daytime, so it gets out. Do you have any feel for efficiency under these circumstances? The tuneup is not far off from what I see as a single big loop and it is much more convenient to use as a smaller spiral. Others with this tuner might like this idea also.

Good point.

Then I suppose the question would be, what does the radiation resistance do when using two or more turns in series?

If it varies the same as inductance (~4X for 2 turns), then it'd be a big win.

The formula for the radiation resistance of a multi-turn loop is given on p. 11 of the document I posted earlier.

http://www.ece.msstate.edu/~donohoe/ece4990notes5.pdf
http://www.ece.msstate.edu/~donohoe/ece4990notes5.pdf

The radiation resistance increases with the square of the number of turns.

As for the loss resistance, as I said earlier, you need to consider not only the increased conductor length, but also the non-uniform current distribution on the multi-turn conductor surface caused by the proximity effect, which will cause underutilization of the conductor surface and thus an increase in ohmic loss.

The following article is a good read for anyone interested in practical multi-turn small-transmitting loops.

http://books.google.co.jp/books/about/Development_of_the_Multiturn_Loop_Antenn.html?id=-s4lOAAACAAJ&redir_esc=y http://books.google.co.jp/books/about/Development_of_the_Multiturn_Loop_Antenn.html?id=-s4lOAAACAAJ&redir_esc=y

The answer to that has already been posted. The radiation resistance is a term to account for the power going into an antenna that is radiated rather than turned into heat. Doubling the number of turns quadruples the inductance and reactance. This cuts the current in half for the same power into the antenna, but it also means a matching circuit is required or must be changed. The halved current reduces the loss in the ohmic resistance. More power is radiated. It won't be twice as much power since the increase is coming from the reduced ohmic losses. But the radiation resistance will approximately double.

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10862. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-01-01 15:10:56 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10862

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Attachments: 2 described; binary payloads are missing from this source WARC

Here are the circuit and block diagrams from the patent (attached).

I own a Twin Coil Ferrite Antenna but it does not work well for me in my situation. I ended up putting up a SW/HF active antenna (RYOAA (eBay)) outside and running the coax inside to a Drake SPR-4 and also a Drake 1260/PRN1000 connected to the stereo.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10867. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-02-01 16:24:07 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10867

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

From: nick.nickrumple@...
Topic: 10868 Message: 10868

Hi All.....I have a question about a 1 meter, capacitor tuned mag-loop that I am building. So far, after a few trial sessions, it works very well. But, I have been reading many online articles from people who build these antennas. While reading these articles, I noticed that many people made the gap at the top of the antenna (where the tuning capacitor connects across) seem like a very big deal. Many of them quoted figures like 25 mm gap. My question is, does the size of the gap make a difference in the performance of the antenna? Thanks for any help you can give.

Ive only made 3 and followed the old one inch gap rule on the last one which is 25mm and on an ali bicycle wheel and it works great, did make one with pipe and plates soldered on the gap which acted as the capacitor so I guess too close will increase capacitance, on the first one the gap was the width of the single variable capacitor I used which was directly connected to the loop and was about 45 to 50mm and that worked fine so more seems OK.Just my findings others may differ? whatever you do once its working you will enjoy it that is guaranteed.73Phil M6MRP

Somebody with more knowledge please correct me...I would say that if the gap is significantly less than the overall diameter it shouldn't matter. I say that assuming that the tuning capacitor is much larger than the distributed capacitance of the loop itself and that the inductance of the loop will not deviate greatly from the design model if the gap is small compared to the overall loop area. So if your loop diameter is 12 inches, you should probably not have a gap more than about 1 inch, but I would think with a 6 foot diameter you could get away with two inches. I doubt that the relationship is linear, it may even be related to the radiator thickness; so I would attempt to make the gap small. However, I know of several loop designs where the main radiator is separated by several inches and wires are connected to the tuning capacitor. The actual gap may be small but the large loop radiator has larger physical gap. Sorry this is not more definitive. If anybody can provide a link to the relevant equations that would be very helpful.

Topic: 10868 Message: 10871

This is mostly from my gut feeling and reasoning, but I present an opposing view. I would tend toward a wider gap rather than narrower. But there may be a lot of leeway.

The ends make a small capacitor, which limits the minimum total capacitance and the maximum frequency to which it can be tuned. If you make the ends very close together, you increase that capacitance and lower the max. frequency and the total tunable frequency range.

For a transmitting antenna, the ends have VERY high voltage so there is a voltage gradient across that gap. Too close, and it will arc.

25mm is an inch. It might have come from an American who used an inch as a round number, which got translated to Metric. What's the breakdown voltage of air? And how large a peak voltage do you have there?

Performance-wise as an antenna, I suspect the gap doesn't make much difference. The high current in the loop follows around the loop and into the wires or straps that tap off to go to the tuning capacitor. Any loop material beyond those points doesn't carry the loop's high current; they just make a capacitor, in parallel with your tuning capacitor. They probably do not radiate anything significant.

Andy

I am sorry I am not sure what everybody is talking about. There is some kind of capacitor physically connected to the "gap" of the continuose loop so the capacitor becomes part of the antenna and circuit. As far as a "gap size", you can connect it directly to the outside of say a "5 inch butterfly capacitor" directly or with a wire or other conducting material. So you could have a "5 inch" gap or less according to which method of connection you use. I have used both and both work well. Maybe for some there needs to be better clarification as to what is the "Gap". Look at MFJ's loop they sell, the capacitor is welded directly to the loop so the capacitor width is the gap. This antenna works very well.

From: gnuarm.2007@...
Topic: 10868 Message: 10874

There are really two gaps in a magnetic loop. One is in the loop conductor which is the part of the circuit that develops the signal you will couple to your receiver. That gap is where the tuning capacitor is connected. But a magnetic loop has an electrostatic shield around the loop conductor. This shield also has a gap, usually at the opposite point in the loop from the gap in the loop conductor so that it can not develop currents to generate it's own magnetic field disrupting the utility of the antenna.

The gap in the shield is what is being discussed here. The capacitance across this gap will be very minute compared to the capacitance of the tuning circuit. Further it's impedance will be very large compared to the impedance of the rest of the shield. I can't say it is inconsequential. I can't however imagine a 1 inch gap will in any way have an impact on the operation of the antenna compared to a longer gap other than the possibility of arcing in a transmitting antenna perhaps.

In a transmitting antenna, does anyone know what potential might be developed across the gap in the shield? I know the loop capacitor can develop very large voltages due to the resonance. But will the shield develop similar voltages? I would think not. The loop has very large currents and the voltage is the counterpoint in the resonant circuit. The shield has very low current due to the very low capacitance across the gap and so I would think the voltage is similarly low.

Rick

From Max again, There is no electrical gap in a tuned loop the gap is filled by a capacitor. A variable capacitor allows the resonant frequency of the combination to be varied. I think you are worrying about nothing. Capacitors are measured in Farads not inches. Make your loop as you are able and enjoy it. Again regards to all.

>>
>> Performance-wise as an antenna, I suspect the gap doesn't make much difference. The high current in the loop follows around the loop and into the wires or straps that tap off to go to the tuning capacitor. Any loop material beyond those points doesn't carry the loop's high current; they just make a capacitor, in parallel with your tuning capacitor. They probably do not radiate anything significant.

10876. Re: [loopantennas] Mag-Loop Antenna question.

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-02-10 10:01:15 UTC
From: Maxwell Mclellan
Topic: 10868 Message: 10876

From Max again. the "gap" in a capacitor is actually filled with a dialectic material, eg air that gives the appearance of a gap, or other insulating materials. It's 9 at night here, I'm going to bed.

Sent from my iPad

> On 10 Feb 2015, at 15:56, "gnuarm.2007@... [loopantennas]" <loopantennas@yahoogroups.com> wrote:
>
> There are really two gaps in a magnetic loop. One is in the loop conductor which is the part of the circuit that develops the signal you will couple to your receiver. That gap is where the tuning capacitor is connected. But a magnetic loop has an electrostatic shield around the loop conductor. This shield also has a gap, usually at the opposite point in the loop from the gap in the loop conductor so that it can not develop currents to generate it's own magnetic field disrupting the utility of the antenna.
>
> The gap in the shield is what is being discussed here. The capacitance across this gap will be very minute compared to the capacitance of the tuning circuit. Further it's impedance will be very large compared to the impedance of the rest of the shield. I can't say it is inconsequential. I can't however imagine a 1 inch gap will in any way have an impact on the operation of the antenna compared to a longer gap other than the possibility of arcing in a transmitting antenna perhaps.
>
> In a transmitting antenna, does anyone know what potential might be developed across the gap in the shield? I know the loop capacitor can develop very large voltages due to the resonance. But will the shield develop similar voltages? I would think not. The loop has very large currents and the voltage is the counterpoint in the resonant circuit. The shield has very low current due to the very low capacitance across the gap and so I would think the voltage is similarly low.

Bill,
Providing you can erect a Flag or pennant away from local noise sources and conductive obstructions within the antennas near-field, then you should get improved reception compared to your current loop.
Points to consider:
Flags require good isolation from the feeder. Hence transformer coupling to the feeder or head amplifier is generally preferred. Commercial products like the Wellbrook FLG100LN uses transformer coupling.

Double KAZ Flags can provide excellent directivity; probably as good a 2 element Flag array. These antennas require a high gain low noise amplifier due to the inherent signal cancellation i.e. the antenna behaves like two end-fire antennas run in anti-phase so as to cancel out the high angle response of the loops.

Other options.

Run two loops as an end-fire array e.g. ALA100 or ALA1530 with a DXE NCC-1 noise canceller as the phase controller
Run two active whips (Clifton Labs) with the DXE NCC-1.

Or the above loops or whips with a twin antenna port SDR that provides antenna phasing.

Note: the DXE NCC-1 can provide the active antenna dc power. So the Antenna Interface/power injectors are not required.

Hi Bill,

The answer is "maybe" and depends on your local noise situation.
People usually buy small loop antennas because they have a deep null and can be rotated to minimize the local noise pickup.
If there is low noise in your neighborhood, than a bigger passive antenna will outperform a small active loop because it has no internal noise source (amplifier).

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10883. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-03-01 14:18:08 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10883

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

10884. Wellbrook or AOR-like wideband RX loop using pre-made circuits

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-03-05 00:37:56 UTC
From: pu3hag.l@...
Topic: 10884 Message: 10884

Hi,

Would it be possible to construct a small broadband loop (1 meter / 3 ft diameter) with performance similar to Wellbrook and AOR using pre-built modules?

What would be your insights?

I'm thinking specifically on using some of the preamps available at
Clifton Laboratories (listed here http://www.cliftonlaboratories.com/current_products.htm
http://www.cliftonlaboratories.com/current_products.htm) PA0RDT mini-whip circuit
(there's a kit on ebay if you search for "activate antenna" [sic]).
KitsNParts RF Amp http://www.kitsandparts.com/rfamp1.3.php
http://www.kitsandparts.com/rfamp1.3.php

This is not an original idea at all...

Mark WA1ION shared some ideas recently here:
http://www.qsl.net/wa1ion/loop/car_roof_loop.htm
http://www.qsl.net/wa1ion/loop/car_roof_loop.htm

Steve VE7SL compiled a couple of ideas (using Wellbrook parts or the PA0RDT circuit with and step-up performance, apud Aldo Moroni)
http://ve7sl.blogspot.com.br/2014/07/wellbrook-loop-plans.html
http://ve7sl.blogspot.com.br/2014/07/wellbrook-loop-plans.html

All inputs are welcome :)

Thanks!

pu3hag huelbe

10887. MFJ Loop fast tuning, maybe too fast?

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-03-10 17:17:57 UTC
From: lavoiejoseph@...
Topic: 10887 Message: 10887

Hello to the group.

I happened to pick up a MFJ-1786 at a local hamfest, I always wanted to try this loop and it just happened that there was one for sale!

My question is about the fast tuning, it seems so fast that by the time the motor slows and stops it has greatly bypassed the resonant frequency and takes a long time, using slow tuning, to go back and get the dip.

For example, going from 18 MHz to 14 MHz the fast tuning takes about 3-4 seconds the controller notes the dip, then slows and stops the motor. I then measure the frequency, using an MFJ tuner, and find that the current dip is around 12.8 MHz. It takes a long time using slow tune, about 30+ seconds to move back up to 14 MHz.

I have more examples, but this happens consistently. Kind of greatly overshooting the resonant frequency and requiring 30+ seconds to go back to get the "dip".

My question is if this is normal or is my fast tuning, too fast? I wish fast tuning went a little slower but I can't find a way to reduce the speed. I know slow tuning is adjustable.

Thanks,
Joe/AB7DP

Hi Joe,Download the manual from the MFJ website. They mention one adjustment possible in the control box that might be applicable:

I don't know if this will help or not but you could try it I would also open a customer support ticket with MFJ and see if they have any info. It takes a couple of days for them to get back to your but I have always received a good response from them with questions about their products. You could also check the Web for other info, I know that lots of people have opened the hood, and I think the controller schematic might be out there as well.

Reduce the voltage supplied to the motor on fast tune a bit. I'm not familiar with the control circuit for that antenna, but I would check the output voltage when in high and then check to see if it is adjustable and turn it down some. But this may slow the slow speed down too. You could also use an antenna analyzer to watch the swr as it nears the frequency you want and then switch to slow speed right before it gets there. Just a thought.

From: qrp.gaijin@...
Topic: 10892 Message: 10894

Hi,

Here's a really simple varactor-tuned loop circuit that I've used for shortwave. The varactor I used is a 1SV149 AM BCB varactor. Note there is a missing resistor in the schematic.

http://theradioboard.com/rb/viewtopic.php?p=34937#p34937
http://theradioboard.com/rb/viewtopic.php?p=34937#p34937

The missing resistor must be inserted between C1 and the anode of the varactor. In other words, both ends of the varactor must go through 100k ohm resistors to the control cable, to reduce susceptibility of the circuit to noise on the control cable. This is explained here: http://theradioboard.com/rb/viewtopic.php?p=34941#p34941
http://theradioboard.com/rb/viewtopic.php?p=34941#p34941 and
http://theradioboard.com/rb/viewtopic.php?p=35092#p35092
http://theradioboard.com/rb/viewtopic.php?p=35092#p35092 .

I'm not saying this is a high-performance circuit, but it's a very simple one that's worked for me.

Best regards,
qrp.gaijin@yahoo.com

Topic: 10895 Message: 10896

The pickup coil should match the input impedance of the radio. That varies with frequency. I have resonant loops with pickup coils covering LW, MW and SW. The SW loops cover a wide range of frequencies. I have multi-turn pickup coils on these with rotary switches to control the number of turns, depending on the frequency. It makes a big difference.

You may also find that the input impedance varies from one radio to another, resulting in slightly different input coil turns.

For LW and MW, the frequency range is generally much smaller and you can usually get away with a fixed number of turns in the pickup coil. That number is most easily found by experimentation.

Bottom line: experiment. Besides varying the number of turns, vary the diameter of the pickup coil. A pickup coil which is too close to the primary coil will tend to interfere with the resonance and Q of the primary circuit. The AN-200 desk-top loop is an example of this. It has a 2-turn pickup coil wound right under the primary coil, which is too close. This antenna is best used when inductively coupled to the radio's ferrite loop.

Hope that helps.

Regards,

Bob in MD

Easy answer, one turn pickup loop, approximately half the diameter of the main loop.

Don't overthink this. It will work fine.

Not sure I understand what's recommended here. I've assumed that the "pickup loop" refers to a secondary coil inductively coupled to a primary, resonant L/C circuit. A cap in series with a "pickup" coil would create a second high-impedance circuit, resonant at some frequency, which then must feed the receiver over a low-impedance transmission line (lead-in). What am I missing?

Bob

I've built several air core loops over the years and always with a one-turn pick-up loop. I think making the pick-up loop any larger will just tend to bog-down the overall Q of the main loop and probably degrade the impedance match to the receiver...nothing to be gained. If you do try it, please let us know what you learn.

Incidently...one time I did try feeding the one turn loop via a fixed mica cap (can't recall the value but probably in the 300 pf range) and it sharpened up the bandwidth of the main loop considerably...it required 're-peaking' more often. I assumed that the 'unloading' of the one turn pick-up loop made a significant increase in the main loop's Q.

You're quite right. Overcoupling will load the primary circuit and lower the Q. That's certainly the case with the AN-200, which I cited earlier. That said, you can still reduce the size (diameter) of the pickup coil relative to that of the primary coil and increase its number of turns in order to provide an impedance match to the receiver. You won't lose any Q doing this. This unloads the primary resonant circuit, and allows it to more or less "freewheel" in space. There is probably a "sweet spot" for the pickup coil - a project for another day.

SW loops, which tend to cover a larger frequency range, have a larger impedance matching problem across their band. For these, I use small-diameter pickup coils having 6 to 12 tapped turns. Addition or deletion of just one turn via a rotary switch has a dramatic effect on output and does not reduce the Q.

I am using a fixed, 3-turn, 8-inch diameter, shielded pickup coil on my LW loop, which I estimate to have a bandwidth of 1 kHz and requires retuning at that frequency interval. The same pickup on MW, probably has a bandwidth of 5 to 10 kH. For my SW loops, I would estimate the bandwidth to be about 100 to 200 kHz at frequencies around 15 MHz.

The proof is in the pudding. They are all microvolt sniffers.

Bob

Me too. I should have given it more thought. You are correct. The series circuit is at low impedance at resonance. When I saw the 300 pf cap in the posting, I just assumed it was fixed and would only resonate at one frequency. There is still a problem however with the lead-in. It would constitute some load as a third component in series with the coil and variable cap. I suppose the ultimate Q would still be provided by the primary circuit. Anyway, it is an interesting concept, which had not occurred to me, and I ought to give it a try.

I don't have a lot of experience with these circuits, but one thing I know is that any part of it can spoil the Q factor. The part where you say, "I suppose the ultimate Q would still be provided by the primary circuit." is not really the right way to look at it. Q is not a quantity that is "provide" like capacitance. It is more the opposite a property that measures the losses and losses nearly anywhere in the circuit will negatively impact the Q.

I don't mean to steer this away from a Q discussion, but thinking about it, caused my memory to kick in. A while back I tried to get two resonant circuits to support one another. I used two SW loops of the same size and brought them into near-field proximity to one another along the coaxial line. One loop was connected to the receiver with a low-impedance coupling coil. As the second loop was brought closer it produced a null signal. I reasoned that this was because the instantaneous polarities of their fields were 180 degrees out of phase. Apparently some folks have gotten this to work by using a relatively small diameter resonant pickup coil positioned coaxially and coplanar with the primary coil.

I do have a MW contraption I built several years ago. It consists of a resonant air-core loop and an active ferrite, balanced loop operating coaxially about the air-core's diameter distance away. The field of the air core loop dominates that of the ferrite core. The ferrite core is set to resonance, then the air core can be tuned to produce very sharp peaks and nulls.

Dexter, Two things.
Question. A well constructed, parallel tuned loop exhibits a high Q. What Q does a well constructed series tuned loop exhibit?
An observation. I made a two turn 6 metre x 2 metre parallel tuned loop hung under the eaves of my garage. The loop ran north/south with its nulls to the east/west. If the loop was tuned to MW station to the west and and a transistor radio tuned to that station was west of the big loop reception on the radio was good. However, if the radio was taken to the eastern side of the big loop the signal from the western station was completely blocked. It was as though the big loop was placing that signal in a bottomless null. Much work has been done using one loop, not much info is available on loops taken more than one at a time. Regards all Max.

Maxwell,

Current flow within parallel- and series-resonant circuits is really the same. At some resonant frequency, inductive and capacitive reactances cancel and current flow is only limited by pure resistance in the circuit. If the resistance is low, the circuit's "figure of merit," or Q is high. For a loop antenna, that equates to a sharp gain in signal strength around the resonant frequency.

The parallel or series circuit refers to the way the tuned circuit is connected to a useful load. For a parallel circuit, the load is connected to the outside of the tuned circuit, one lead at one connection of the coil and capacitor and the remaining lead to the other connection of the coil and capacitor. When the circuit is at resonance, it presents a very high impedance across the load; and when not at resonance, a low impedance. The load may have an incoming signal attached to it and the parallel-tuned circuit acts as a gate or switch to pass (high impedance across the load) or shunt (low impedance across the load) the signal.

In the case of the series-resonant loop antenna, the circuit between the coil and capacitor is broken and the load (lead-in to the receiver) is inserted between them. At resonance the amount of resistance in the circuit is higher than it would be with just the coil and capacitor forming the circuit. Consequently, the Q would not be as high.

In the case of a loop antenna having a "free wheeling" tuned circuit coupled to the receiver with a separate pickup coil, it should not be viewed as either a parallel- or series-coupled circuit, but rather transformer coupled. There is still a load on the tuned circuit, and thus an effect on the Q. This is determined by the degree of coupling between the primary and secondary coils.

Hope this helps some. I will try to get to your observation later on.

Regards,

Bob

Hi Bob: the easy way to undestand is to think like two resonant coils forming a transformer.
the capacitor and coil are a paralell tuned circuit. it exibit the quality to respond to the tuned
freq. (more sensitive at res freq.) and the pickup loop is to match the impedance btwn radio, transmission line and the antena. thats why is only one turn o may be part o a turn. this not necesarilly match impedances but
you can improve the system with a capacitor in serie with the pickup loop to help in the matching process.
Paralell circuits is a high impedance and series is low impedance. this is a elementary explanation.
try to get a good electronics theory book to gain akcnoledge in this topic.

For reception only, the thumb rule is abt 3 to 5 % of paralell number turns. if there are a few turns maybe
one o half turn will suffice.

From: dannibou@...
Topic: 10915 Message: 10915

I uploaded a photo of my loop with the green wire pick-up loop. This is what give me the best signal vs Q. It's a two turn pick-up. Originally, the pick-up loop was close to the main winding. The result is higher Q with the smaller pick-up loop for almost the same signal on my kenwood R-2000. I'll try to upload another photo of my loop with the pick-up loop before the mod.
Danny

Bob, thanks for the theory.I tend not to use a pickup loop but prefer a capacitor to tune the main loop and use a capacitive division setup for matching. The type of setup as used in the MFJ -936B loop tuner but with just two variable capacitors and none of the bells and whistles of the MFJ. Regards to all Max vk2tti.

10917. dielectric question

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-03-29 08:57:14 UTC
From: dx11
Topic: 10917 Message: 10917

Hello all,

At last I have started the design of the transmitting magnetic loop I want to build. Most of the design choices still have to be made, like dimensions, loop material and construction.

But I intend to make the adjustable capacitor myself. This to avoid the variable air capacitors or vacuum capacitors that are hard to find or expensive and do not have the right capacity range.

I want to be able to have control over specifications like capacity range, voltage rating and dimensions. A few concepts have arisen from my search to solutions.

I am thinking of using a dielectric between the capacitor surfaces, (a) for increasing the capacity for a given surface area because of the relative permeability an (b) for increasing the voltage rating.

But I need to avoid the risk of introducing losses and of heating the dielectric.

What physical property of the dielectric should I look for? Could anyone point me in the right direction?

Or can I find a list of materials I could use for this dielectric ?

I hope you can help.

Cor PA4Q

Adrian wrote:

"Does anyone have an idea why gmail AUTOMATICALLY sends group mail to spam folder?"

I am guessing you are talking about Gmail, and about messages going to your spam folder on your Gmail account.

It doesn't happen with mine.

Each person's spam filtering is unique. It may be that you had received a lot of spam, that trained your spam filter to think these messages are spam too.

If you are depending on a Filter you created, to keep them out of your spam filter, it denies your spam filter the chance to 'learn' that they aren't actual spam. Your spam filter learns mainly from you clicking on the "Spam" or "Not Spam" buttons. But it can be maddening when it takes the spam filter a long time to re-learn.

When those messages did go to your spam folder, Gmail tells you why it thinks they are spam (e.g., are they similar to other messages you marked as spam? Did they come from the same domain as other spam? etc.) I take those hints with a large grain of salt, but they might help give you an idea of why it thinks they are spam.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10925. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-04-01 13:09:40 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10925

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Guys,

I just posted in the files section "80 Meter Horizontal Loop Antenna" that discribes the process of tuning the loop and experimenting with a Balun Design's 2.5:1 and a home brew 4:1 balun and a final length of 275'. I am very please with the results and hope the information will be of some value to the members on this list. This is the closests thing to a multi-band HF antenna that I have seen yet

Sal,

The 80M loop replaced a 80M Windom. I also have a 6' active RX loop and I find the 80M loop to be just as quite as my active loop on most bands. To date I have only made a few DX contacts, but have been able to work any station that I can hear and I am only running 100 watts.

Everett,
Interesting to hear of your new 80m loop.
I had a 40m version in the shape of a diamond at 30ft, feed point
was at the South sharp point with a quarter wave of 120 ohm twin line.

Worked like a dream on 40 – 10m, 248 DXCC countries wkd / cnf with 5 watts SSB
only from a TS-130V, great days !!!!

A word of warning, loops attract static and though we don't get many storms in
NW UK I had a number of hefty belts off the antenna over the years.

Regards,
72, Brian, GØNSL-QRP.

EXCELLENT results, Everette! I was also surprised to see that the 4:1 balun worked better than the 2.5:1 balun. But no matter, you have it working as well as could be expected.

I've been wanting to do a horizontal loop, this is pushing me in that direction! Thanks for publishing these results of your work.

Hi Brian,

Thanks for the reply and your comments re: static concerns. The 4:1 Balun that I am using is a current type and therefore electrically shorts static charges. I also have a very good earth ground before it enters my house. Also as a cover all I always remove the antenna from my rig when not using it.

Everett,
Excellent safety system you have.
When the sky darkens here I drop the loop on the lawn hi!

What first made me aware of the fact was during one approaching storm
I had shut down the station but could here this ‘ ticking ‘ noise, looking around in the gloomy
shack I could see sparks jumping from the body of the SO-239 antenna socket to the center pin
at the wall panel where I plug in the rigs patch lead.
That was when I started lowering the loop to ground !!!!!

72, Brian, GØNSL- QRP.

Can I gain some advice off the group regarding Mag Loop construction

wish to know is it better to use a vaccum variable cap Or Butterfly cap?
reliable place to purchase vaccum variable cap based off user experience?Vacuum Variable Capacitor 10-500pF
since the vaccum variable is copper and sealed should a copper loop be used?
if I go with a butterfly cap should I use an aluminium loop? if rotor stator are also aluminium?
price for Butterfly cap that will give a good capacitance range (rotor and stator only)10-500pF
Loop construction, was thinking of using a three roller jig or are there any U.K hams that have
locally sourced solutions was thinking of around 22mm dia tube?
TX power out will be approx 150w

73s for now

G4xcp

Butterfly cap is no different from other variable caps. A variable cap is a variable cap. I had a supply of tuning caps from junked radios. Air core vs. sealed with insulating plastic (transistor radio type) - no difference. The resistance of the wire is hundreds of times more important than capacitor leakage. I will warn you about very old butterfly caps and very old air core caps - they were more linear, and tuning the loop on the high end of the dial is next to impossible. All of my very old caps are sitting in the bin unused. Look for caps with the shaft towards one side and the plates small on one side and large on the other.

Most transistor radio caps top out about 250 pF. You can extend that by putting the oscillater section in parallel, but you won't reach 500 pF. My one and only 500 pF variable came out of an early 70's European receiver that had longwave. It does make it easier to construct a loop, but you can usually get the entire AM band if you switch a few turns of wire in and out. It really isn't that big of deal - using a loop is pretty interactive with the tuner and loop being tuned separately, flicking a switch for frequency range on the loop is just a minor step. If you are lucky enough to find a tuning cap out of a tuned RF radio, it has a section you can parallel with the antenna section to get more capacitance. Instead of 365 pF max, you get 730! Of course the high side doubles, too, so you might need a switch on the cap sections.

I take the opposite approach. The point is that you want the highest L/C ratio possible. It's the coil that captures the signal, so you want to make the inductance of the circuit as high as possible. The cap is just there for resonance. If you're using more than 200 pf, you can do a lot better.

A good way to use an old 2-gang variable is to connect the sections in series. The metal frame becomes the common connection. This reduces the total capacitance in half and raises the frequency range for a given coil. You can then wind more turns on the coil and increase its so-called effective height, AN, where A is the area of each turn and N the number of turns. Connecting an SPST switch across one gang will short it out, double the capacitance, and lower the tuning range. Another way to do this is to put a small trimmer cap in series with the variable. Either way effectively gives you a 2-band antenna and, in the process, gives you some much needed bandspread at the high end of the tuning range.

There is a limit to this. Every coil has distributed capacitance, a point at which it is self-resonant, and it cannot be used in a tuned circuit beyond that frequency. I try to get the top frequency of the antenna as close as possible to the self-resonant point of the coil. The down side of this is stability. Adding just a picofarad of capacitance at the high end will significantly detune the antenna. This can be produced by body capacitance. That's were some mechanical considerations come into play, isolating the capacitor from the knob.

Some of the old single-section variable caps sold by Hammarlund and E.F. Johnson are also quite good. I'm using one on shortwave which covers 14 to 23 MHz and only has a max of 30 pf.

Regards,

Bob

Hi, reading your web page I see where you indicate the radiation pattern is different for a spiral wound loop than for a solenoid wound loop (what you call edge wound). Can you provide any references on this? I can't picture how the antenna would operate completely differently just by changing the small aspect of spiral vs. solenoid winding.

Picture a large loop with windings spaced fairly close together. I think the image of how the magnetic fields form and interact are intuitive to most experiences in electronics. I can't see how changing the spacing of the wires from a solenoid configuration to a spiral configuration (a very small change in how they interact) can possibly reverse the position of the nulls and the nodes.

Is there something I am missing?

Rick

I believe you are correct. Nulls are along the axis of the coil, regardless of the coil being in the shape of a solenoid or spiral ("pancake loop"). Think of the response pattern being a doughnut with an infinitesimally small hole.

Incidentally, distributed capacitance of a coil is minimized when it is wound as a spiral. In theory this allows you to maximize the L/C ratio and effective height for any given band of coverage. Having a negligible thickness they are also easier to construct.

Regards,

Bob C.

Why do you say the distributed capacitance is lower with a spiral? Picturing the same image of a large coil, I can't see any reason why the capacitance would be appreciably lower with one than the other.

As to construction, I think that depends on many factors. The antenna I built (but not yet tested) was made with small boards (1x3 I think) and the wires wound around the ends of the boards. I think winding a spiral would have been much harder in this case.

Many years ago, I had access to a well stocked engineering library, and
put it to good use when I started building loop antennas. This little
nugget on distributed capacitance came from "The Theory and Design of
Inductance Coils," by V.G. Welsby, John Wiley & Sons, 1960, p. 145.
"The self capacitance is directly proportional to the length of the
coil, thus leading to the conclusion that, for a given space, the type
of solenoid which will have the least self-capacitance is a flat 'disc'
winding, extending practically to the centre of the coil."

I start with crosses made from strip wood, 3/4" x 1/2" for LW and MW and
3/8" square for SW. I pre-drill holes at 1/4" or 1/2" intervals before
assembly. The coil is thus wound tennis-racket style through the
holes. This makes for a very light-weight antenna. Light weight is
also important if you want to balance the coil so it can be rotated
vertically as well as horizontally. Details are provided in
Electrically Small Resonant Loop for Shortwave (Oct '14).pdf and
Electrically Small Resonant Loop for Medium Wave.pdf in the files section.

Some solenoid designs have "shoes" attached to the ends of the cross
pieces so that the turns can be spaced an inch or so apart, thus
decreasing the distributed capacitance.

From: caodwolf@...
Topic: 10943 Message: 10943

Hello everyone. I have recently been bitten by Ultralight AM craze after listening to a presentation at the NASWA Shortwave Fest. I have a small commercial loop antenna and want to build my own using PVC piping. There is a good article written by Gary DeBock on this.

The one piece I am struggling with is what kind of wire to use. I want 18 gauge stranded which is what the article references but am finding this a little overwhelming as to where or what type I should obtain. I've read of some using Litz wire, copper enameled wire and then even speaker wire.

I Google this and get a bewildering range of stuff. I would appreciate if someone could assist and steer me in the right direction. Building the thing looks pretty straight forward but I assume if you don't use the right type of wire your DX can suffer. My interest is in the AM band.

Thanks in Advance

Mr Carters' response was only partially true when he states that caps are the same. There is a HUGE difference between a vacuum variable and a plastic insulated variable that he mentions. Buterfly caps are used in a particular configuration that essentially creates a center-tapped capacitance.

I think is comments, and perhaps others are given from the perspective of a receiving-only loop.

The reference you have, calling for a vacuum variable cap is specified that way so it can be used to transmit as well. The big advantage that vacuum variables have is very high RF voltage capability. THis is a must.for transmitting circuits where the off resonant voltages can be in the kilovolt range. Quite simply, the small receiving caps will meltdown and evaporate when used in a transmitting environment--perhaps causing damage to the transmitter as well.

So...if you are building for Rx only, use what you have....if you want to make it for Tx as well, better use the right stuff.

From: gnuarm.2007@...
Topic: 10936 Message: 10947

I did some significant research on this a while back and I don't recall stranded wire being any better than solid unless it is Litz wire where each conductor is insulated from the others. The issue I believe is the skin effect where the AC current mostly flows near the surface making the apparent resistance of the wire higher than the DC resistance. This increases losses which lower the Q and therefore the strength of the signal.

The skin effect also limits the useful diameter of the wire. So I can't imagine needing 18 gauge wire. Litz wire is usually specified with two numbers, the number of strands and the wire gauge of each strand. I believe there is also braided Litz wire which I'm not sure the reason for. I think it may provide more event current distribution in the conductors.

David,

I've built many tuned and untuned loops over the Years for MW/LW and for the MW band the best I've found is Litz that has multiple strands of 46 Ga. wire. It's usually described as ga/nn where ga=gauge of conductors and nn=number of conductors in the wire. The small gauge minimizes the skin effect at MW frequencies and the more conductors the lower the resistance and the higher the "Q" of the tuned circuit. I've found that for most air and small ferrite core loop antennas the expense and hassle of anything over 46/100 isn't worth it but for Ferrite Sleeve Loops and high Q coils 46/660 will make a big difference. YMMV. I get mine from mkmak222* on Ebay, decent prices and I've never had a problem.

Don't expose Litz to the weather or direct sunlight for long periods. The wire is very thin and so is the insulation and protective coating. I learned this the hard way :(

*I don't know the vendor personally nor do I get anything for mentioning them. I'm just a satisfied customer passing along a reliable source for Litz Wire.

Ultralight DX https://groups.yahoo.com/neo/groups/ultralightdx/conversations/messages A discussion area to support the growth of Ultralight MW Radio DXing

View on groups.yahoo.com
https://groups.yahoo.com/neo/groups/ultralightdx/conversations/messages
Preview by Yahoo

"Ultralight" is defined by the size/volume of the radio (per the group standards) and several other features (no SSB capability, for instance). "Barefoot" is using the radio as-is, no modified ferrite or loop antenna. The DX part comes in when one takes advantage of propagation trends/windows to catch and identify broadcasts not normally available in one's listening area, including from other countries.

There are many radios that qualify as "ultralight", one of the new ones and already a favorite of many being the CCrane Skywave.

Tim

Regarding stranded vs solid vs litz wire.
Litz wire is made of individually insulated strands of wire bundled together. It comes in anything from very small bundles of very fine wire, to very large bundles of still rather fine wire for use in high power high frequency.
This is because of the skin effect, where at higher frequencies the current tends to travel only in the skin of the conductor.
The problem with regular stranded wire is that at higher frequencies with the wires in electrical contact, the wire begins to act more like a slotted solid wire. So it actually reduces the effective surface area.
For receiving loops, I'm not sure any of this makes a huge difference in distance as much as it does in selectivity. People here more qualified than I can make statements about that.

I just did a casual calculation on my longwave, 80-turn spiral loop of 22 AWG stranded hookup wire. The outer turn is 36" on a side and the inner turn 8". I found the coil to contain approximately 147 ft of wire. The Q is sharp enough to require retuning every 1 kHz. I would suspect the bandwidth (-6 db) to be something less than that. It would be interesting to note any difference using Litz wire. Perhaps the skin effect is significantly less from 150 kHz through 450 kHz.

I have at various times used a MW loop to help transistor radios when signals were weak. Usually it was made from pre-used enamelled copper wire removed from some dead component wound over wooden cross arms and with little or no spacing. A s/h twin gang tuning capacitor was used. for tuning.

Sometimes radio would go on platform at base, other times a link coupling turn was used with the same single strand copper wire twisted to make a "transmission line" to a coupling loop round radio or ferrite rod.

Whether using Litz wire would have made a significant difference I have no idea. Too high a Q would probably have resulted in sideband cutting with poorer audio.

Biggest problem for me was trying to keep the wires tight. Any ideas for keeping single stand enamelled wire taut?

Cheers,
Will

I'm not an expert on the electronics of tuned loop antennas, but if you construct one with the wires taught and it becomes loose, that means your frame has changed shape or size. I know wood can change shape and size when the humidity changes and to a lesser extent when the temperature changes. You might consider a different material or perhaps use an adjustment on the frame that allows you to lengthen one of the arms to make it taught again. If you don't mind a bit of additional complexity, I can picture one arm with an elbow hinge in the middle and a turnbuckle to the adjacent arm to pull the elbow and lengthen the arm. Do they make plastic turnbuckles? I think a metal one might not be the best idea. If you can't buy a plastic one, you can always make one easily enough. It's just a block of plastic with tapped holes and a couple of screws.

Rick

Without doing the calculations I would say at 150 kHz, the Q of an antenna using 22 ga wire is limited by the skin effect. I worked on a 60 kHz antenna using RG-6 coax which uses an 18 ga inner conductor and the skin effect was definitely in play. I couldn't easily change the gauge so I was fine with that. But with your antenna both the frequency is a lot higher while 22 ga is not a lot smaller than 18 ga, so a smaller wire could have been used with no ill effect on the antenna.

The skin effect is not absolute. The profile of current is a smooth curve from the outside to the center. But once the radius of the wire passes the skin depth you are reaching a point of diminishing returns using fatter wires.

Rick

Hey Will;

All wire will stretch a bit with time, to various degrees, and will cause sagging in a loop. This is implicitly a restatement of the "Rope Around the Earth" problem, and it doesn't take very much wire stretch to distort the winding shape:
http://mathforum.org/mathimages/index.php/Rope_around_the_Earth
http://mathforum.org/mathimages/index.php/Rope_around_the_Earth

The question is: Do you feel that this is changing the loop performance, or is it a question of aesthetics?

In either case, the suggestions offered by Rick will help. Alternatively, simply re-tensioning the wire by pulling it around the frame as a matter of routine maintenance may be all that's required for a loop which will primarily be used indoors, as seems to be your situation. At some point, the wire may settle down, and the stretch vs time should slow down for copper wire as it's cold worked.

Loops which are permanently sited outdoors are a different matter. I have used remotely tuned outdoors loops for years, and twice a year PM is absolutely required here in Chicago. The wire here is generally 10 AWG type TEW, and outdoor loops just seem to be a magnet for perching birds and flying squirrels (if the loop is sited near a tree). Windings are re-tensioned in the Spring and Fall, and just allowed to sag away between these PMs with very little noticeable effect on loop performance. By far, the bigger variations in performance (tuning range and Q) can be attributed to changes in temperature and humidity.

Hope this helps, joe

No expert here either - just some seat-of-the-pants, long-term observations. My 80-turn, LW loop, which tunes 150 to 420 kHz, as reported, has approximately 147 feet of 22 AWG insulated, stranded wire in the main coil. I used pine lattice stock for the cross pieces. These were drilled at 1/4" intervals (diagonal) to thread the wire tennis racket style, so the turn separation is somewhat less than 1/4".

Note: This antenna is at least 30 years old. None of the coil turns have any noticeable sag or are touching. If I had to say, I would guess I used about 10-lb of tension as I laced the turns. The cross pieces are slightly bent from the lacing process, as I did nothing to prevent this, and they have not changed position in all that time. I took no precautions to allow for thermal expansion. The assembly has been quite forgiving of minor impacts and shows no signs of damage or deterioration.

I have a somewhat smaller loop I use on the lower end of the MW band. The frame is made from 3/4" stock which is notched instead of drilled to receive the wire. I used solid bare copper wire on it. Same result - no slack or damage for many years.

Bottom line: I would say seasoned wood has enough give to it to provide the required structural strength and flexibility for a long time, and there is not much need for any extraordinary precautions.

Bob

You could probably use some precision laboratory equipment to determine the precise Q of various coils, or perhaps do a side-by-side test under controlled conditions - both beyond my capability. My thought with larger wire has always been the tradeoff you would reach with distributed capacitance. As stated earlier, I like to maximize the L/C ratio and operate the coil as close to its self-resonating frequency as possible. In that approach, distributed capacitance is wasted capacitance. Then too, fat wire adds weight.

Thanks for thoughts.

Using pre-used wire, usually pretty thin maybe 24 gauge, it is difficult to get any tension in the wire. Add in the change in dimension of the wood used as frame it is very difficult to keep taut.

It doesn't have any effect on reception as the loop has to be tuned every time station is changed.

Its main problem is that it makes it very difficult to clean the dust off.

Slightly off topic I have used similar wire for a windom a/e. It survived several hits from small birds that I saw. It was made for about 1900khz but worked well as SWL a/e for all frequencies, BC upwards.

Cheers
Will.

With a multiturn loop, as you pull tight and wind on more and more turns, the frame is compressed and previous windings become loose.

Solution, simply don't wind so tightly. Pull the wire just tight enough to avoid sagging.

Loose turns must be a problem unique to solenoid coils. I have never had difficulty with slack when winding spirals - the Stradivarius of loop antennas. I start with the outer turn and work inward. The first turns are adjusted to hold the cross pieces rigid at right angles. The result is a relatively rugged, compact, light-weight coil with low distributed capacitance.

Would you use the inner of the hardline as loop with the outer shield
cut at top as shield OR use the outer shield as the loop with inner not
connected. The larger diameter would more closely replicate copper tube.

Cheers,
Will

Hi

I would think that 1-inch CATV hardline will work fine as a loop antenna. Corrosion at
contact points may be problematic. I would recommend you make soldered connections
to the Aluminum.

To solder to the Aluminum all I do is apply some high-temperature grease to the surface
to be tinned to block Oxygen from the to-be-soldered region, scrape the surface below the
grease to remove existing oxidation and then use a BIG high-wattage soldering iron to
continuously scrape/heat the region to be soldered while feeding regular solder to the area
being tinned.

EVENTUALLY, you will build-up a solder-blob that is electrically and mechanically well
attached to the Aluminum. Once this is accomplished, you can easily solder copper wire to
the blob to make connections to connectors.

My experiments with soldered connections in a somewhat ocean-breezy influenced
environment showed no degradation of the joint after a year of being 'outside' in the WX.

Using hardline for transmitting loops is very practical.
As with all Tx loops, high currents will flow on the outer surface so a large surface area is best.
Hardline is preferable to plumbing copper pipe because no soldered joints are required (except where the capacitor is connected), thus a lower resistance to high RF currents can be achieved.
Hardline is plastic coated copper so it is protected from corrosion.
Hardline is easy to bend into a loop and is rigid enough to keep its shape.
Best regards, Derf Mockford, G8ZGK

Hello All,

Has anyone had any experience using a receiving loop with a regenerative ham receiver?

Regens have a real attraction since they are so simple to build. But, they are notorious for blocking and pulling in the presence of strong adjacent channel signals. It occurred to me this afternoon that the added selectivity and directionality of a high Q receiving loop might be a real advantage when used with a regen station receiver. Has anyone had any experience with this combination on the air?

Cheers,

Well, sort of. Not a receiver per se, but I have an active loop antenna for MW, which I built about 30 years ago. This is a center-tapped balanced ferrite core loop which feeds a dual FET amplifier. The amplifier is the one designed by Ralph Sanserino about 40 years ago. I think the FETs go into an emitter follower and go out to a low-impedance line to the receiver.

I modified Sanserino's circuit to provide some positive feedback (regeneration), which is controlled by a pot. Yes, it does what it's supposed to do, providing some extra gain and higher Q. I can't say it isn't overkill, but it's interesting.

Hello All, Has anyone had any experience using a receiving loop with a regenerative ham receiver? Regens have a real attraction since they are so simple to build. But, they are notorious for blocking and pulling in the presence of strong adjacent channel signals. It occurred to me this afternoon that the added selectivity and directionality of a high Q receiving loop might be a real advantage when used with a regen station receiver. Has anyone had any experience with this combination on the air? Cheers, Brian Burns Ex: W5BRO, K6UCD

Well actually I designed the amplifier, not Ralph Sanserino. Ralph
manufactured and sold loop antennas with a wooden frame he designed.
Ralph, unfortunately, is no longer with us.
The original circuit is on my site
<http://www.jlkolb.cts.com/site/dif_fet.pdf>
I believe the circuit was first written up for publication
by Grant Manning in LWCA (Long Wave Club of America)

It would be interesting to see the regen modification.

John,

I was unaware of your involvement, and you are to be congratulated. The balanced, high-impedance input is the key and provides minimal load on the tuned circuit. Those amps work equally well on small ferrite loops. I also built one without regeneration for portable use.

Somewhere, I must have a sketch of what I did for regeneration, and will try to find it. We got busy raising kids, working, and all of the usual things, and it is only the past couple of years I have started to unpack my previous life.

Thinking about it, I doubt whether the feedback went all the way back to the loop. That might be the best way to go - perhaps to a small feedback coil on the ferrite.

I contributed to LWCA in its very early days. Corresponded with the late W.R. McIntosh.

Is this the same circuit as he used on his 'Radio West' ferrite bar loops, with changeable inductors? I have this version which used 5 ferrite bars which I later modified and added 4 more bars to, extending it to 22". I also have a smaller single bar one that he made, exclusively for the BCB. What was unique about these was his PCV alt / az mount which allowed the bar to be rotated in almost any direction for nulling....amazing little table-top antennas.

From: gail21@...
Topic: 10985 Message: 10985

hi
I am new to loop antennas and wish to ask those that have built mag loop antennas which gave good all round results with fewer re tunes of the cap.

areas I am focused on are either a double loop (one loop behind the other)
or a figure of eight loop with the tuning cap in the middle
I have 7/8ths copper tubing (22mm) which i have purchased on a roll and
also a vaccum variable capacitor 10-500pf

band coverage will be from 80 mtrs to 20mtrs which would be the best type of match a faraday loop or a gamma match has anyone built an auto gama match as well as tuning the capacitor?
any advice from constructors much appriciated

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

10987. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-05-01 13:10:40 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 10987

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,

10988. Highest Q loop configuration

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-05-03 18:50:54 UTC
From: Brian Burns
Topic: 10988 Message: 10988

Hello All,

As nobody seems to have any experience using a loop with a regenerative receiver (not surprisingly), let me put my question a different way. What sort of passive loop design has the highest Q?

I'm looking to the loop antenna to add some selectivity to a regenerative receiver by way of its directionality, and narrow bandwidth. So just the opposite from people that are looking for designs that don't need to be re-tuned very often as you change frequency, I'm looking for a design that needs to be retuned as often as possible!

Any suggestions would be greatly appreciated (:->).

P.S. I'm pretty capable with mechanical fabrication of things.

Cheers,

Brian Burns Ex: W5BRO, K6UCD

10989. Re: [loopantennas] Highest Q loop configuration

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-05-03 22:23:04 UTC
From: Richard (Rick) Karlquist
Topic: 10988 Message: 10989

Assuming you want 10 kHz bandwidth, the maximum
usable Q is only 54 at 540 kHz ranging up to
170 at 1.7 MHz. These Q's are fairly easy to
achieve if you make a shielded loop out of RG-59
video coax with a copper braid shield. Or of course
you could use hardline. The Q is more or less
independent of loop diameter, but is proportional
to conductor diameter.

Having said that, it is possible that selectivity
may be limited by reciprocal mixing due to phase noise
on the "oscillator". A regenerative receiver is an
oscillator. It is not clear whether the loop antenna
is going to be the tank for this receiver, or if there
will be a separate tank. I believe that this tank
has a similar Q limit, but I don't know much about
regenerative receivers. In any event, it is trival
to achieve the Q's I mentioned above using a Fair-Rite
toroidal core with 61 material.

10990. RE: [loopantennas] Highest Q loop configuration

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-05-03 23:41:46 UTC
From: Brian Burns
Topic: 10988 Message: 10990

Hello Rick,

Thanks for the reply to my query!

I'm thinking mainly of 40 meters and up to 15 meters. The receiver that I'm planning will have at least one RF stage, so the detector will be isolated from the antenna by that. There is even the possibility of a separate BFO so that the detector won't have to go into oscillation to receive CW.

Regen's are intriguing for home brewers because they are simpler than superhets, and you don't have to worry about birdies and images, and finding IF transformers. But---they are notorious for blocking and locking onto strong signals in adjacent channels. A high Q loop could provide some additional selectivity up front, and of course if you are lucky enough to have the guy you want to hear, be in a different direction from the interfering station...

So, anything I can do to increase the Q of a small loop up in the bands I mention will be all to the good. I'm willing to put up with having to retune the antenna frequently.

Thanks again!

73,

Brian

You should probably use hardline for the loop.
As the loop perimeter approaches 1/3 of a
wavelength, the Q will be limited to a few
hundred due to the radiation resistance
becoming significant, IE an ohm or two.
If you tune with varactors, they will probably
be the limiting factor on Q.

In terms of making high Q inductors, my experience
with a Q meter was that on one occasion, I was
able to pin the meter at Q=1000, using a 6 inch
diameter coil at 14 MHz. That was my "personal
best" at building inductors. Loops tend to have less
Q. In general, you rarely see a measured Q at HF
much above 500. QST had an article called "field
day filters" about 40 years ago that used helical
resonators. You are probably better off doing that
rather than trying to get "free" filtering with a
loop antenna.

From: Dexter
Topic: 10988 Message: 10992

I think you're on the right track, Brian. I have some small loops working reasonably well up to 23 MHz. I find that the Q is high enough to significantly reduce or eliminate strong image signals on old single-conversion "boat anchors." In other words, what would be a 910 kHz image is well outside the bandwidth of the antenna. That may be a good test.

The key to high Q is to minimize the load on the primary tuned circuit. Imagine an ideal L/C circuit resonating freely in space with no load. In practice, you can approach that by using a relatively small and properly placed pickup coil which is also matched to the impedance of the transmission line to the receiver. I do this with switch-selectable turns on the pickup coil, which matches the impedance at various points along the tuning range of the primary circuit.

In /*theory*/, wire size affects Q to the extent that larger wire has lower resistance at resonance. However, in /*practice*/, considering the relatively short length of wire involved, I have not found wire size to make much difference. I think I reported here that my LW loop consisting of approximately 147 ft of 22 AWG stranded wire must be retuned every 1 kHz. That's high Q.

Expect the bandwidth to increase with frequency. At 15 MHz, it may be on the order of 100 to 200 kHz. That does not necessarily mean the Q is low.

Regards,

Bob C.

Not to be a wet blanket, but if you're aiming to increase the ability of a regenerative receiver to receive weak signals in the presence of "strong signals in adjacent channels", I'm afraid a loop antenna won't do much for you. There's just no way you can build a single tuned circuit (which is what a loop antenna is) in front of the regen that can be sharp enough to give you single-signal selectivity. You might get some very mild improvement against the strongest signals in far-away adjacent channels, but for strong signals a few kHz away I don't think you're going to be satisfied.

It might be fun to play with, but I don't think you're heading down a path that will actually lead to high performance. If your goal is really to improve performance, consider a traditional superhet architecture and see these post by Dave Newkirk:

Why would a pickup coil present any less load to the antenna than another properly matched attachment? Is this just a practical issue of being the easiest way to match the load?

What other coupling method were you thinking of - possibly a series-resonant circuit connected directly to a transmission line? In that case, the characteristic impedance of the transmission line is in the circuit and would contribute to the total resistance at resonance, thereby lowering the Q.

The coil in a "freewheeling" L/C primary circuit forms a transformer with the isolated pickup coil and there is no "load match" to speak of, just the degree of coupling you want to achieve. My experience is that there is a "sweet spot" where increased coupling significantly begins to degrade Q.

Hello Rick,

"QST had an article called "field day filters" about 40 years ago that used helical resonators. You are probably better off doing that rather than trying to get "free" filtering with a loop antenna."

Thanks for the excellent tip! I had seen something about "Helical Resonators" a couple of years ago, but no details. QST April 1973 is the location of the article.

I've had something of the same idea with the design of an antenna tuner with large, high Q coils made from copper tubing. I've got plenty of space for one, and it would certainly look appropriate for a retro appearing regenerative receiver! Also, regens are famous for gain and sensitivity, so insertion loss would not be a problem.

Thanks again!

Cheers,

Brian

I don't recall the details, but I have seen coupling circuits using capacitors and I think I have seen at least one using a balun. The impedance of the transmission line will never lower the Q other than through the dielectric dissipation or wire resistance. The Q of an antenna is the ratio of the reactive component to the dissipative component. Reactive components can't dissipate (other than parasitic effects) so they can't lower the Q.

There is nothing magical about a pickup coil. The receiver still constitutes a load and will affect the Q of the antenna if enough power is drawn. A transformer is *exactly* a load matching circuit or more correctly an impedance matching circuit. I'm not so familiar with the coupling aspects, but I expect a looser coupling results in a lower percentage of the power being transferred to the receiver (not a good effect) resulting in less impact on the antenna Q (a good effect). I suppose there is a happy medium somewhere giving max voltage to the receiver.

I seem to recall there was a web page or document available on the web with several loop antenna coupling circuit examples which were from the ARRL handbook.

Rick

https://groups.yahoo.com/neo/groups/regenrx/conversations/messages/23027
<https://groups.yahoo.com/neo/groups/regenrx/conversations/topics/19210>

I’m a great fan of Dave Newkirk’s, and have gotten the same advice directly from him. I have an HBR-11 just waiting to be rebuilt, and an HQ-150 that is in good working condition. Still, the regen has its attractions:

“Regen's are intriguing for home brewers because they are simpler than superhets, and you don't have to worry about birdies and images, and finding IF transformers.”

Rick’s suggestion of “Helical Resonators”---essentially high Q antenna tuners---seems a likely way to get some selectivity up front, and have Byron Goodman smile upon me from up in ham heaven.

Cheers,

Brian

Has anyone ever tried to use the 2-turn pickup coil on an Eton/Grundig/Tecsun AN-200? It's wound directly under the primary coil. I'm not sure what was intended, but it's a good example of what happens when you overload the primary resonant circuit - very low Q.

From: gail21@...
Topic: 11000 Message: 11000

would like to ask the group for information on examples of the thickness of material for both the Faraday section of the magloop or the gamma match thickness in relation to the main loop size.
is there a formula for the thickness of coaxial cable used in a faraday. for example if the main loop has a diameter of 22mm or 7/8ths is this factored into the calculation of the matching smaller loop that has the coaxial socket on it?
same question with the gamma? does the thickness of the faraday have any bearing on tx bandwidth?
hope this makes some sense, there are plenty of calculations for the main part of the loop but very little on the smaller section?

Hi until last month (for about 5 yrs) I have used a 23m longwire with a MFJ-971 tuner into an IC7000 with no problems. Except on a couple of occasions the vswr went unstable. This was fixed by operating the coil tap switch, which seemed to bring it back. I recently turned the longwire into a 50m diamond shaped loop sky wire at 6m height. I connected to the tuner with 3m open feeder from one corner. I connected this to the balanced feed to the 4:1 balun on the MFJ971.
All bands gave reasonable VSWR.

Last night I was setting up to operate on 80m i had a strong smell of burning and found that the switch tag to the coil was floating in a pool of burnt switch insulation. The vswr was too large to use.

This raises a few questions.

1. Have i designed and /or connected the loop sky wire in an incorrect way.

2. Are individual MFJ components available to purchase.

3. what simple tests can be done next time before using it to Tx. I do *not* have access to any fancy antenna analysers

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11006. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-06-01 13:28:44 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11006

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11007. Commercial magnetic loop antennas

Yahoo group: loopantennas (2013 — 2017)

From: ell_vis@...
Topic: 11007 Message: 11007

Hi all,
I haven't been able to find any old topics about this on the forum. I'm sure there is a way to access that but this is what I'm looking for. I would like input on all available Magnetic loops (reasonable cost) that are sold retail, like the best performance for the buck, most HF freq bands, ease of use, easiest to hide for HOA and appear to work the best or maybe something as simple as a place on this sight that already did some comparisons. Even if you say, we can't help you here thats not what we do.
Either way Thank You All,
Jerry
P.S. I'm new here and thanks for letting me be in the group.

There is another group, at least one other, about just Magloop antennas. This group is more general. I know you are talking about Magloops, but do you mean those for transmitting, or just reception?

This group (like most others) is composed of individuals, so you'd be asking for opinions of those individuals, not a group consensus. My observation on this is that the vast majority of people who have bought something commercial tend to favor what they bought, or at most have compared two brands, but usually not more. It is uncommon for someone to have tried half a dozen different models of something like a Magloop antenna.

But I could be wrong.

(Me, I like to build things myself. But I haven't done much of that lately. It's on my list.)

Andy

It sounds like you are asking about transmitting loops. The physics of transmitting loops are very discouraging, and no vendor is going to change the laws of physics. The loop efficiency and bandwidth will both be dominated by size. The bigger loop will always win. Make the biggest loop you can out of "invisible" wire that will work for your HOA. Ignore marketing claims for smaller loops made out of large tubing, copper strap, helical windings, etc. Bigger is better, up to a conductor length of one-third of a wavelength. (Above that, the loop acts something like a Moxon dipole).

I have a big screwdriver antenna with a 102 inch CB whip on top of the coil on my van that I would venture to say would outperform any loop you can buy. If I lived in an HOA, I would just operate from my van and/or run a coax line from the van to the house and use the van antenna from the house.

Thanks Rick,

It just seems like the loop should work being in a small space like an attic, the say YouTube never lies about their videos.:) I have given thought to the idea of a screwdriver antenna but I think I would have to weld a mount to the undercarriage of my small car and only use it when I can. That’s why I’m trying to set it up as a base station and leave it connected all the time. I still maybe need to trade or sell my Yaesu FT-100MP and buy something a little more light weight in a portable. Thanks for the advice I will keep it in mind.

Jerry - no sign yet

11012. Multi Turn Loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-06-04 13:15:46 UTC
From: tenorman1952@...
Topic: 11012 Message: 11012

I've built small receiving loops, and know how the size and number of turns affects them. But I've taken an interest in the "skywave loop".

This may have been asked and answered before, and I missed it, but please bear with me and allow me to ask again.

What happens when a full wave loop, a single turn around say, 280' around (full wave on 80 meters) is doubled back, so instead of a rectangle 70' on each side for 280' total, it is now two turns with 35' on each side?

How does this affect impedance?

Any other effects I should be aware of?

The reason is, of course, the 70' on a side rectangle will not fit in my yard, but a smaller loop would fit.

73,
Paul - AE5JU

From: Andy
Topic: 11012 Message: 11013

I think I've mentioned this before, though I should point out that this is a mental exercise and I don't have the theoretical proof to back it up.

Small (i.e., "magnetic loop") multi-turn loops work because the length of wire is much smaller than a wavelength, so the current in each turn is the same and in-phase. The effects of the turns add to one another.

Larger loops don't do that. If you take 1 wavelength of wire and loop it into a 2-turn loop with a 1/2 wavelength circumference, the current in each turn is exactly opposite to (180 degrees out of phase with) the other turn. This would tend to make their effects cancel, rather than add. I think.

But, with antennas, it never hurts to try.

I did do a series of EZNEC simulations some time ago, trying 2-turn and multi-turn loops that were less than a wavelength in size but not considered "small" loops. (Trying to fit a loop antenna into a small lot.) The results were so disappointing that I did not pursue it further.

Andy

Of course a non rotatable dipole, especially in an attic, is
a compromise. It is even more compromised if you load it
up on bands where it is more than a half wave. Then you
get narrow lodes interlaced with nulls. On 40 and 80
meters, a low dipole tends to be almost omnidirectional.
I used to have a low dipole that ran north and south
(ie beaming east and west) but on 80 meters it got out
extremely well to the north and south.

I haven't tried the 2 turn loop yet. However, SGC says in their book that a
2 turn loop works with their tuners. Also a 3 or 4 turn loop but that is ,
I suspect, going to limit how well over 2 turns.
CEBIK also wrote about a IL-ZX two turn loop for 40 meters. Although his
two turn loop was basically a folded dipole fed back on itself in a loop
but fed on opposite sides at the feed point- thus it had a twist.
I plan a 2 turn loop for 40 meters(18 foot on a side) to try to improve
reception. I will also try it on transmit.
Anything to decrease the received noise, thus better signal to noise ratio.

Hello Dr. Don,

By all means keep us informed on this one! I've had the exact same idea for quieter receiving, but mainly for some directional gain on both TX and RX.

My shack is located at the very narrow end of a triangular lot that restricts conventional antennas to broad-siding in a north-south direction, and living on California's north coast a mile from the Pacific I would like to be able to work toward the east.

Cheers,

Brian

I haven't tried the 2 turn loop yet. However, SGC says in their book that a 2 turn loop works with their tuners. Also a 3 or 4 turn loop but that is , I suspect, going to limit how well over 2 turns.

This may have been asked and answered before, and I missed it, but please bear with me and allow me to ask again.

What happens when a full wave loop, a single turn around say, 280' around (full wave on 80 meters) is doubled back, so instead of a rectangle 70' on each side for 280' total, it is now two turns with 35' on each side?

How does this affect impedance?

Any other effects I should be aware of?

The reason is, of course, the 70' on a side rectangle will not fit in my yard, but a smaller loop would fit.

Paul,
You might like to use the free antenna simulator program mmana-gal to try out various antenna configurations. It can show you the impedance, gain and propagation pattern of the antenna dimensions you enter.
It is available at http://hamsoft.ca/pages/mmana-gal.php

Ive used that trick at work... in the field with antenna runs.... When there was too much cable... you would make it into a loop... however, when you are up at higher frequencies the coil becomes an significant inductance.... To cancel out the loop you take the large loop and twist into a figure eight and fold it over on itself. Half the coil running one way and half running the other way cancels out the inductance of the coil and whatever effect it had on the frequency in question... In this case it was around 608 - 614 MHz. Medical telemetry.
I guess twisting a large loop into a figure 8 and folding it cancels out noise?? Best Regards Phil

I haven't tried the 2 turn loop yet. However, SGC says in their book that a 2 turn loop works with their tuners. Also a 3 or 4 turn loop but that is , I suspect, going to limit how well over 2 turns.CEBIK also wrote about a IL-ZX two turn loop for 40 meters. Although his two turn loop was basically a folded dipole fed back on itself in a loop but fed on opposite sides at the feed point- thus it had a twist.I plan a 2 turn loop for 40 meters(18 foot on a side) to try to improve reception. I will also try it on transmit. Anything to decrease the received noise, thus better signal to noise ratio.

Thanks, Ray. I had tried a few other antenna analysis programs, but none showed how to enter anything into them, that is, how to draw in an antenna and make the program work. Never figured out how to use the programs. Talking about EZ-NEC and one from South America that sent me a beta and keep wanting me to use the program. I'd like to, don't know how.

I'd appreciate someone showing me how to make these programs actually work.

PS to the bit on the garage loop. I also made a two turn transmitting loop for 20m. Tuned using a MFJ-936B loop tuner. The turns were made from two, one metre, lengths of aluminium strip 12mm x 3mm cross connected to form a two turn loop, also works well. further regards Max vk2tti.

G'day Paul. I have, hung in the vertical plane, on the side of my garage, a loop 6metresx2metres using twin core speaker cable, connected to produce a two turn loop. It can be used tuned or untuned. Its null is east/west and receives north/south up and down the New South Wales coast. Receives the HF signals from the Sydney to Hobart Yacht Race at armchair quality, you can almost smell the salt air HiHi. Seriously it works well. Give it a go. Regards Max vk2tti.

I've had a multiturn loop with 22 Ga wire, total length of wire 160m, diameter was about 20 feet (you please do the math on how many turns that is), about 12 feet up, in operation for about half a year with 10W. Worked on 40, 20m and other bands with SGC 211 tuner (can't remember the other bands, know that 30m did not tune), worked 80m with my transceiver's tuner.

Had plenty contacts.

8 turns?

Watching this thread reminded me of what my EE Adviser told me when I was a Research Assistant for him.

Paraphrased, it was many Moons ago...

"Do the calculations and model all you want, when it comes down to it radio and antennas in particular operate on FM so you never what it's going to do until you build it"

He was not referring to Frequency Modulation BTW. ;)

8 turns sounds right. I remembered that it were around 6 or so, it were certainly many. It really was an experiment out of necessity at the time. I never dared to put more than 10W in on digital since the SGC211 does not take it. I did put 30W SSB through on 80m with fair results on a State net, not all ops were able to hear me with those parameters.

G'day Paul, the big 2 turn loop I have only received on. The small two turn loop is used for 20m ham band on both Tx and Rx. The small loop with MFJ-936B tunes from 10 to 17 MHz but is not able to achieve a good match to 50 ohms at each end of that range. Regards Max vk2tti.
PS Ihave a SGC 237 tuner that would probably tune the big loop but I havn't tried it.

Thanks Marcus,

~ I had the 160m multiturn loop oriented horizontally, given that diameter was around 10m in a stealth setup…Thus null straight up, no directionality in horizontal plane.

I've never worked either 160m or 80m, but would certainly like to have a rotatable loop for 40m, even if it had no gain, just directional lobes that could be aimed.

Cheers,

Brian

Marcus / Brian,

For many years I used a 40m full wave loop in the
Horizontal mode at a height of 34ft and it worked fine out to 3,000
miles plus then I installed a reflector under the loop at 17ft so 17ft
spacing and it worked the world !!!!
243 DXCC countries worked / confirmed with 5 watts SSB from
a Kenwood TS-130V.
A great antenna, I must try a multi turn version.

72, Brian, GØNSL.

Hi Brian,

I have a 80 meter loop and would be interested in how you had, or have your loop set up with the reflector and how you are feeding the loop. I am using a 4:1 current balun on mine and feeding with coax. I am able to use it on all bands 80 through 10, including the WARC bands, with the exception of 30, which requires a tuner.

That’s amazing Brian!

Would love to know more about the reflector as well. Was it a closed loop of wire or an open loop of wire?

Not mentioned until now, was my experiment with a grass level loop antenna (maybe it’s of interest to some):
http://kd0jkm.blogspot.com/2012/06/k3mts-grasswire-antenna-idea.html

Brian; Your placement of a REFLECTOR under a horizontal loop is interesting!!

I have two loops, both same-sized for 75 meters:
One is at 40 feet height off the ground.
The other is at 20 feet height off the ground.

The 40 foot height one is TOTALLY IN THE CLEAR, supported by masts in an open field.
The 20 footer is clear of the trees, but is somewhat close to trees, and encircles a series of trees. (Maximum clearance is 15 feet, minimum clearance is 6 feet.)

The higher one has better signals (than the 20 foot height one) by about 2 S-units, RX and TX. This reference is on 75 meters, but 20m and 17m might also suffer.

Is there HOPE to add a REFLECTOR to the 20 foot high loop? I cannot get it higher; It is supported mainly by the trees... As for a possible reflector, I'd need to dig it into the grass under the loop's wire. (No hope, no "function," if it is buried..?)

Thank you! -Mike- K0JTA

Hi

I modeled this full-wave loop with and without the lower loop at 17-feet
using EZNEC
and it is a most *uninteresting* antenna and not one I'd waste any copper
on . . .

Hello Brian

Regarding your ===>
Dick,
* There are occasions when antenna theory falls on its face.*
The antenna worked here !!!!
* 72, Brian, GØNSL.*

Yes, you are somewhat correct, but I've modeled many antennas, built them and they performed as modeled . My expectation of an antenna is for it to have a fairly low TOA with a minimum of energy directed nearly straight up.

Your H-loop with the lower loop/reflector directs most of the energy upward at TOA's above 60-degrees which is fine for local area "Nets". Yes, it does radiate at low angles but at markedly lower levels compared to the higher TOA's : gain is ~4.6dBi at 90-degrees and 5dB lower at 23-degrees.

[image: Inline image 1]
Your H-Loop expected VSWR behavior:

[image: Inline image 3]
Now, here is a simple 34-foot tall vertical with only four 34-foot long radials - much less copper and about the same gain at 23-deg TOA as your loop. This antenna has about 0.4dB LESS gain than your loop at 23-degrees TOA but is easier to install using only one 34-foot tall support versus one for each corner.

[image: Inline image 5]
If 8-radials are used the gain at 23-degrees TOA increases to -0.31dBi which is more than the horizontal loop using about the same amount of copper.

[image: Inline image 6]
I adjusted the wire lengths a tiny bit to position the resonant point around 7.15MHz . Here is the expected VSWR for the 8-radial vertical

[image: Inline image 7]
All of the radials are modeled to be 0.1-foot above ground because EZNEC V5.0 does not deal well with radials touching or embedded in the ground.

The slightly re-scaled wire lengths to position resonance around 7.15MHz results in a slight gain improvement: gain ~ -0.24dBi at TOA = 23-degrees.

Being more DX oriented, I would build the simple vertical antenna to take advantage of the low TOA and reduced level of the more local station signals due to the null at 90-degrees TOA.

For the more casual operator your loop is probably the better one to use since it approaches an NVIS in its behavior.

Dick, your info is very interesting.
Yes for DX the vertical is a better antenna.
However local noise may be a problem in an urban location on receive.
Here in Ecuador I have no local contacts on 40 or 30 meters.The nearest active ham is 40 miles away.
Most hams, less than 200 country wide,operate 20 to 10 meters, except for local country wide net on 7060 at 7 PM local time nightly.
Therefore most of my contacts are over 3000 miles from my QTH.

I currently have a 66 foot doublet at 75 feet above average terrain fed with 300 ohm line and tuner.
A 40 meter loop at 45 feet fed with coax and a 88 foot inv "L" center fed with 300 ohm line.
The "L" has the feed point at 40 feet AGL and half vertical and half sloping horizontal.

When the conditions were good, the last 4 years, the horizontal doublet was the best antenna 40 to 10 and the inv "L" second. The loop was quieter on receive and used primarily as Rx antenna.
Now with reduced condx the "L" is always the antenna of choice for contacts 40 to 17. Higher sig levels by 2 to 4 "S" units. I use the "L" because I don't have adequate room for a good radial system with a vertical. The "L"is often lower noise than the horizontal doublet.

I plan a 44 foot inv "L" soon as a backup to the 88 footer. BTW, I worked Europe and Japan and ASIA on 80 meters with the "L" and 100 watts. I also plan to convert the 40 loop to a 2 turn RX antenna.

For someone operating casually in the states, the loop is probably the best all round antenna. But for DX,and all my contacts are DX, the vertical or inv "L" is hands down the better antenna.

Dick,
Thank you for the very extensive ‘ expose’ of the horizontal
loop antenna and for one who has never modelled an antenna in 40
years of ham radio quite an eye opener !!!!

I can recall a long 40 minute contact with a 9X5 station on 15m who was an engineer for
Deutsche Welle
and him asking about ‘ angles of attack ‘ from my loop, I was lost hi!

Regards,
72, Brian, GØNSL.

11051. Re: [loopantennas] Highest Q loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-06-16 16:32:57 UTC
From: Richard (Rick) Karlquist
Topic: 11049 Message: 11051

To get the highest Q, you should use the largest round
conductor to build the loop. For loops of circumference
above something like 1/10 wavelength, the Q tends to be
limited by radiation resistance, and it is not necessary
to use a huge conductor.

You should also not put the wire inside of a PVC pipe.
That will lower the Q. If you want to use PVC pipe, then
cover it with copper tape wound axially (not helically),
and use the copper as the conductor.

Hello again Rick,

~ If you want to use PVC pipe, then cover it with copper tape wound axially (not helically), and use the copper as the conductor.

~ Rick N6RK

So, if I understand you correctly, you would use wide copper tape in one large turn around the outside perimeter of the circular PVC form? Would the copper tape have to meet electrically, edge to edge on the inside of the loop?

The widest adhesive backed copper tape that I could locate was 3 inches wide. Even on Amazon it was expensive, because it was being sold in minimum 36 yard lengths.

Cheers,

Brian

You can bend PVC pipe when it is heated up. Bends easily---but the problems of fixturing it, heating it all up, keeping it warm, handling it, and keeping it from collapsing will make you crazy.

Up to about an inch or 1-1/4 in diameter, there are some other, thin-walled water tubing that will bend in a diameter of 24 inches or so without collapsing.

This seems like a lot of effort.

Copper tubing can be purchased that is dead soft for bending. Up to at least 3/4 or 1 inch in diameter. It can be easily formed.

Alternative is get the size coper tube you need, fill it with sand, put on end caps and have it roll formed into a loop. metal fab shops do this all the time. Motor cycle frame shops or racing roll cage guys typically can do this up to 4 or 5 inch dia tube.

Several pieces of tape, where each is one large turn around PVC, and
overlap them so that the PVC is fully covered in copper.

>

You want highest Q, use copper. Home Depot sells aluminum tape that
might be cheaper. It will theoretically decrease Q by 28% vs copper

Brian Burns wrote:

"Am I right in assuming that to get the highest Q (and narrowest bandwidth) possible in a magnetic loop, I should use small gauge wire inside a PVC pipe support structure?"

By "small gauge wire", did you mean a small number (like 10-gauge or less, even 0- or 0000-gauge)? Or did you mean a small (thin) wire?

I think the Q is dominated by the resistance of the loop's conductors (over any geometric effects). Therefore, minimizing resistance loss is essential for getting good efficiency and highest Q. Increasing the surface area reduces the resistance.

There's all sorts of magnetic loops out there; but for the folks who are really serious about using them for transmitting, most tend to use copper pipe, the fatter the better (except for the effect on their wallets).

Andy

Hello Bob,

I too use narrow-band (high-Q) loops between 0.15 MHz and ~23 MHz to the exclusion of almost everything else. I would think anyone wanting a broad-band antenna would be building a loop for all the wrong reasons.

Bob C.

I think I accidentally hit the send button, and sent you a blank reply!

I plan on using the loop with a regenerative receiver, and am looking to get selectivity by "whatever means necessary". Short of going to a superhet (;->).

By the way, is there a rule of thumb for voltage developed across the tuning cap by a power level in watts? I'm thinking of using my loop with a QRP transmitter putting out 5 watts.

Cheers,

Brian

Hello Rick,

~ You want highest Q, use copper. Home Depot sells aluminum tape that might be cheaper. It will theoretically decrease Q by 28% vs copper

~ Rick N6RK

I'm beginning to think that copper tubing looks like the best and easiest solution after all. Is there an optimum tubing diameter for the HF bands, or is it just a matter of the larger the diameter the higher the Q?

I'm sure all this has been gone over before---thanks for saving me the trouble of digging through the archives (:->)...

I am far from an expert on tuned loop antenna, but when I looked into the design principles some time back, I was constantly reminded that too high of a Q will limit the bandwidth to the point that it restricts the bandwidth of the received signal. Since the relationship between Q, operating frequency and bandwidth is a relative thing, maybe your frequency is high enough you won't have that as an issue. But if you are talking about using copper tubing for the antenna, you might want to check your calculations to see if this might be a concern.

My application was for the WWVB signal at 60 kHz. So while it would be easy to narrow the bandwidth quite a bit at that low frequency, the signal only needs some 20 Hz, so it was not a problem with the wire I was planning to use.

But if you are talking about using copper tubing for the antenna, you might want to check your calculations to see if this might be a concern.

Thanks for the reply!

My plan is to use the loop for QRP ham receiving with a regenerative receiver and a 5 watt transmitter on 80 meters and above. I'll be using CW, and trying QRP AM as an experiment.

Minimum bandwidth on AM is about 3 KHz, and on CW it's probably 500 Hz, depending on the stability of the receiver. So at those frequencies the antenna Q would have to be astronomical to cause any problems.

Cheers,

Brian

This is true for circumferences less than about 0.1 wavelengths.
Above that, you can get into a situation where the Q and efficiency
reach the point of diminishing returns and you might as well just
use 12 gauge wire or something.

A really big loop made out of wire will blow away a smaller one
using huge copper tubing. Loop area trumps everything else.

Lol, define "astronomical". If you are talking about using copper pipe, then you may well achieve some very high Q factors. 80 Meters is not all that high a frequency.

I'm just sayin'...

Anyone worked this out before?

11066. RE: [loopantennas] Highest Q loop

~ Lol, define "astronomical".

The definition of Q that I use is the bandwidth at the 3db down points, divided into the center frequency. So if we figure the bottom end of 80 meters as 3,500,000 Hz, and 3,000 Hz as the narrowest permissible bandwidth for AM, then the antenna Q would have to be greater than 1167 to cause a problem.

Hmmm, that’s a good deal lower than I thought. What sorts of Q’s do well-made copper loops achieve? This is getting interesting---especially for use with a regenerative receiver.

Cheers,

Brian__

I'm frequently confused whether these threads are about receiving or transmitting loops. If transmitting, just let me know, and I will go back to copying the mail.

My goal has always been to maximize coil inductance (effective height). In a resonant circuit, that involves minimizing distributed capacitance. This invariably results in a multi-turn spiral (pancake) coil wound with hookup wire. Q seems to take care of itself. At 400 kHz, for example, I would estimate the bandwidth to be less than 1 kHz, while around 20 MHz it's on the order of 100 to 200 kHz. These are different loops, of course. You can do the math to see what kinds of Qs these are. Body capacitance will significantly detune my LW loop. However, I don't detect too much attenuation of sidebands from European and N. African LW AM stations. In spite of a -3 db bandwidth, the skirts of the bandpass still flare out.

"What sorts of Q’s do well-made copper loops achieve?"

There are a few loop calculators on the net. The two more well-known ones I know of are:

http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
http://www.aa5tb.com/loop.html (http://www.aa5tb.com/aa5tb_loop_v1.22a.xls)

For 80 meters and a 20 foot circumference (6.4 foot diameter) loop made out of 1 inch copper pipe, the first one says the Q is 1407 and the bandwidth is 2.49 kHz. The second calculator is in close agreement, with a Q of 1389 and a bandwidth of 2.519 kHz.

The efficiency of such a loop is 11-12 %, so nearly 90% of your power goes into heating up the copper pipe. And this doesn't account for other losses, such as the tuning capacitor. But those other losses help improve one's bandwidth by lowering the Q.

Measuring Q of an actual antenna is something else entirely. Many people seem to want to approximate the Q by looking at the points where their antenna's SWR is 2:1. But 2:1 is entirely arbitrary and it has no meaning for Q. If the antenna were being fed by a matched impedance source, the SWR would be 5.828:1 at the half-power (-3dB) points. But transmitters do not look like a matched impedance source. One person on the net argues that it looks more like an ideal voltage source (an idea I do not agree with), and therefore the response at SWR=5.828 would be -6dB instead of -3dB.

Just about nobody has the means to measure when the actual field strength is -3dB from the center frequency; and even if they did, it's uncertain what the transmitter would produce for power output as the antenna's SWR varies.

I guess what one really ought to do is use a fixed test signal that contains a (noise-like?) range of frequencies, and then use something like a spectrum analyzer to analyze the radiated emissions and derive how those signals are affected by the antenna's bandwidth.

Andy

Hello Brian,

You can also use PEX, sold at Home Depot & I suppose Lowes (I work at HD). Its a a little over $5 for a 10 ft piece and very bendable. Comes in 1/2 to 1in dia. and in 3 colors, Red, White & Blue (I know patriotic, but its Hot, feed and Cold) Easy to use.

Heat works ok, but electricians also use bending springs for 1/2" and 3/4" PVC. They work well. Both electric supply shops near me have springs and short lengths of pipe near the counter for people to play with while they're waiting. Possibly yours does too so you can see for yourself how well they'll work. PVC in a spring doesn't go like copper or brass, where you slowly exert force and the metal moves. You need to push really hard until the PVC starts to move; after you reach that point it bends with a lot less force.

Steve,

I've changed the topic, so as not to bother the hi-Q folks.

Holes are drilled along the cross members at 1/4" intervals.
As the outside turns are approximately 3', that would make the cross members approximately 4'3".
With 80 turns, they will be wound nearly to the pick-up coil in the center.
I calculated the total length of wire required a few months ago and seem to recall it being in excess of 400 ft. That should produce some measurable resistance, but the resulting Q is truly amazing. I used several short pieces of 22 AWG and soldered them together as lacing progressed.
Best to anchor the cross members on a big piece of plywood while you lace the turns. That way you can more easily pull out slack and keep the frame relatively square. My loop is about 30 years old, and the primary coil is still relatively taut.
My pickup coil is shielded based on old theory I read at the time about low-impedance, direction-finding loops. I'm not convinced any longer that shielding a pickup coil is necessary for nulls. Based on my recent experience with SW pick-up coils, I should go back and revisit the LW pickup coil design.

I have not spent a lot of time DXing NDBs. My main interest at the time of construction was picking up trans-Atlantic BC stations here in Maryland. Depending on propagation, there are four or five regulars.

As you know, noise can be a killer on LW. This antenna will dramatically reduce or completely null it, especially if you include variation of vertical orientation in the mounting arrangement.

Regards,

Bob C.

Attachments: 1 described; binary payloads are missing from this source WARC

I recently finished constructing a helically wound 19 foot diameter loop for 80 thru 30. It is constructed with 3.5in OD flexible corrugated irrigation pipe and a PVC frame. I helically wound it with 44 feet of 3in wide .008 copper sheet. All my mechanical copper connections are silver plated and the gamma match is silver soldered. My bandwidth for 1.0 to 2.0 SWR is 4 Khz on the low end of 80 and almost 20 Khz on 40 and 30. I know there is a lot of controversy regarding helically wound loops vs solid copper but mine works great. If nothing else I am able to use a lower capacitance VVC for the loop diameter than I would for say a loop of say 7/8 heliax. A picture of the loop is on my QRZ page. I am attaching a pic of the SWR curve from my analyzer, don't know if it will come through on this reply.

Interesting!! I had never heard of this!! I had heard of laying the reflector on the ground as ONE PIECE OF WIRE that is in the form of a loop, but three pieces of wire..???? (Is the reference for a three-side loop?

> //
> /I would certainly try a reflector under your 40ft high antenna./

//I am OK with the 40 foot loop. The loop that is 20 feet off the ground works OK, but it is one S-unit lower than the co-located 35 to 40 foot height loop.

It is for this reason that I wanted to see if anyone had info on (first of all), if such a low height loop (at 20 feet)m can be improved! -By adding a reflector, as an example.

> //
> /There is a G station that is a farmer and uses a single horizontal
> loop antenna, /
> /3 full waves on 160m around his moorland site, the signal is awesome/
> /though only 20ft high !!!!!/

//My loops are for 75m. I have had many LARGER loops, the largest being well over 2000 feet. They were OK, but not good on 75m. I finally learned to model antennas and READ what the modeling was telling me. It became apparent that a 75m loop was the king, which I finally proved to myself. (I am a slow learner, and had always stuck to the bigger, higher as the terms to adhere to with antennas.

Hi Andy,

I'm sure you meant 19ft circumference! Anyway, you are right, the main advantage of a helically wound loop is increased inductance, which enables a smaller capacitor to be used for a given frequency, or a smaller loop for the same size cap. The tradeoff is a little loss in efficiency, which is not terribly significant. A while back I compared two copper and one helically wound loop to a reference dipole, using the Reverse Beacon Network for comparisons, with interesting results. Section 4 on my QRZ page has the results, if interested. The bottom line is that a helical loop of the same diameter as a 1" copper loop exhibited about 1.5dB less efficiency, and 2.5 dB less efficiency than a 3" copper loop.

By the way, I recommend you measure the bandwidth of your loops at an SWR of 2.6. This corresponds the the -3dB points on the bandwidth curve (7dB return loss.) Of course, this is only accurate if the SWR minimum is very close to 1:1.

Enjoy your loop!

Paul

Thanks Paul,
Extremely interesting and informative. Yes--I meant 19 foot circumference. I currently have a very high current 350pf VVC in customs-should be here next week. I am also waiting for all the parts for the automatic Stepper controller I am building. I was going to just put it on the helically wound loop but I just might use some of the excess 7/8 Andrews heliax I have laying around and see how that performs.
Looks like I might need a 8 foot loop to get me on the low end of 80 with the 7/8 hardline and 350pf.

A while back I compared two copper and one helically wound loop to a reference dipole, using the Reverse Beacon Network for comparisons, with interesting results. Section 4 on my QRZ page has the results, if interested. The bottom line is that a helical loop of the same diameter as a 1" copper loop exhibited about 1.5dB less efficiency, and 2.5 dB less efficiency than a 3" copper loop.
>
> By the way, I recommend you measure the bandwidth of your loops at an SWR of 2.6. This corresponds the the -3dB points on the bandwidth curve (7dB return loss.) Of course, this is only accurate if the SWR minimum is very close to 1:1.

11078. Negative Noise Figure loop Amplifier

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-06-26 11:28:16 UTC
From: Andrew Ikin
Topic: 11078 Message: 11078

Hello Group,

Approximately 8 weeks ago fellow group member Steve Ratzlaff and I had an discussion about the noise performance of amplifiers for Non Directional Beacon work. Steve suggested that it may be a good idea to look at the Antenna Amplifier noise floor with a simulated antenna inductance, rather than using a resistance equal to the amplifier input z.

Steve's suggestion makes perfect sense when one considers that the real and radiation resistance of loop antennas are very small in comparison to the loops inductance.

First I retested two active antennas; Wellbrook's ALA100 and ALA100LN in the paddock using 20m circumference loops. Loop area 21 sq.m. Both antenna use noiseless feedback. The ALA100 uses Bipolar transistors, the ALA100LN uses JFETS.

The gain comparison on MW/LW was an increase of 2-4dB in favour of the ALA100LN.

Unfortunately the ambient noise level was too high to see any noise floor difference.

Next; Bench Tests (gain and Noise Figure NF of both ALA100 amps.) were conducted using a Marconi 2019A Sig. Gen. and WinRadio Excalibur. A 9dB Norton amplifier in the Antenna Interface was used to ensure that the total gain was approx. 10dB higher than the Excalibur NF. Thus to ensure that the higher amplifier gain would mask the receiver NF affecting the measurements. A 20uH inductor was used to simulate the loop’s reactance.

The NF was measured using the gain method i.e. the excess noise above the amplifier gain when the input is terminated with a resistor. The negative NF is measured with a inductance connected to the amplifier input.

Both ALA100s have an approx. 50 Ohm resistive input z as determined using an Array Solutions AIM 4170C Antenna Analyser.

WinRadio Excalibur set 1kHz BW and the S Meter to RMS AVG.

-144dBm is used as reference for the 1kHz BW

The negative NF is defined as the amplifier noise being less than the increase in noise due to the amplifier gain.

Test results.

Old ALA100 1MHz gain = 27dB (18dB with Passive Interface)

Noise with 50 Ohm input = −116dBm

NF = 1.0dB

Noise with 20uH input = −118dBm (-127dBm with Passive Interface)

NF = −1dB.

New ALA100LN 1MHz gain = 28dB (19dB with Passive Interface)

Noise with 50 Ohm input = −116dBm

NF = 0.0dB

Noise with 20uH input = −124dBm (-133dBm with Passive Interface)

NF = −8dB.

3 other ALA100LNs were tested, the worst case was a -6dB NF.

Looking at the above one can see that there is only a 1dB difference in the gain and NF of the two Head amps with a 50 Ohm input.

The apparent -1dB NF of the ALA100 with the 20uH input is probably due to the fact that Inductors are noiseless compared to a 50 Ohm resistor.

However, what is striking, is the apparent high negative NF of the ALA100LN. My first thoughts were when this showed up, that the gain had dropped by 8dB because of the loop inductance and this would show up as low antenna gain. However, the on air comparison suggested that this wasn't the case. Also Dave Aichelman ran some comparative tests confirming my observations.

I do not have an explanation yet as to why the ALA100LN has an apparent negative NF or why the noise floor drops by 8dB, but it certainly accounts as to why some users are seeing improved performance. The theoretical NF of the ALA100LN is close to 0dB.

One could speculate that there is a significant mismatch of the antenna noise from its real and radiation resistance being a small fraction of the amplifier input z. However, I have only been able to achieve a significant negative NF using JFETS.

The ALA100LN uses 8 x J309 Fets. with noiseless feedback.

The negative NF can be increased to approx. -10dB by altering the feedback and increasing the amplifier gain. Also the negative NF increases by a couple of dB where the loop inductance is higher e.g. a 20m circumference thin wire loop (30uH). Also the negative NF is maintained as the frequency rises.

The ALA100LN has a sister, “Florence” the FLG100LN with an input matching/isolation transformer of 1152 Ohms for Terminated loop antennas e.g. Flag and KAZ. However, the antenna termination resistance makes the negative NF feature unrealisable.

One may ask what is the significance of the amplifier having a negative noise figure of -8dB?

It basically means, that there is the potential of an 11dB s/n improvement when compared to a conventional amplifier of the same gain and NF of say 3dB with a similar loop size. This feature could be used to compensate for any mismatch loss over wide bandwidths.

Additionally the negative noise figure could compensate for usual NF degradation when loops are run as close spaced Phase Arrays.

I am currently exploring to see if the apparent negative NF can be exploited with smaller loops. To this end I have extended the bandwidth of the ALA100LN from 10MHz to 30MHz by

configuring the FETs to run in cascode with two Bipolar devices. However, there may be a bandwidth limitation due to the fixed input impedance of the amplifier compared to the ALA1530 with its loop/amp. impedance tracking verses frequency.

Andrew,

The apparent negative noise factor is *probably* a result of the low DC resistance of the inductor effectively damping the noise generated by any semiconductor junction. I don't have the schematic for the ALA100 but I'd bet the majority of the noise comes from the G/DS junction of the input J309s getting amplified in the following stage(s). Try a short across the input and see if you get a similar result.

Experimenting with tuned receiving loops I've found that the noise is much higher when using a high impedance amplifier on the tuned section and can be pushed below the atmospheric noise floor on LW/MW by using a small, low impedance pickup loop with an air wound or a single turn or 2T center tapped for balanced output on a ferrite feeding a high impedance common source input stage. That may fly in the face of "conventional wisdom" but it works.

Tim,

The amp. without the loop has a low dc resistance due to its input transformer. When the loop is disconnected the noise is at its lowest. Similar designs using bipolars can a have say a −1 or −2dB NF. Dmos fets e.g. BS170 do the opposite and have a +8dB NF.

JFET's, unless MOSFET's, DMOS, or epHEMT, have virtually no
current noise, just the shot noise of the gate current.
This current is often picoamps. There voltage noise is the same as
whatever a resistor would have if its resistance were equal to the
channel resistance. The effective noise temperature (in
the optimum circuit) is in the few 10's of Kelvin. I have actually
measured this. If you parallel a lot of JFET's or use ones with large
geometry (essentially the same as paralleling) the noise voltage
goes down as sqrt(N). The noise current goes up, but was
almost nothing to begin with. The limit of what you can
do with this technique is due to the build up of capacitance.

When you use JFET's, the idea of a "conjugate" match or matching
for maximum power transfer is not applicable. Basically, the
JFET is an open circuit input and connects to your transducer.
A low noise amplifier is always mismatched to the source.
In any event, a loop antenna always has an inherent noise temperature
of room temperature due to the Johnson noise of its copper resistance,
and the best any amplifier can do is to add negligible noise to
this resistance. The extreme low noise temperature of the JFET
goes to waste here. You can do just about as well with a bipolar
transistor. Do not use a MOSFET or epHEMT because the 1/f noise
is bad.

The idea that "the noise goes up less than the gain of
the amplifier, so therefore NF is negative" is due to a misunderstanding
of NF.

Rick, thank you for your comments and explanation. I did use the word “apparent” negative noise figure and did suggest that there is a mismatch situation. However, I am not aware of any bipolar transistor design that would be as useful in this application.
The main point I am trying to make is, that by using JFETS for a loop amplifier there is the potential of realizing lower noise compared to more conventional designs.

Good evening all visitors to the group.
I would plan to buy the Spare Loop Amplifer of Wellbrook 1530 Ala or Ala 1530LF, to make a loop amplified with lower spending. Someone to tell me if Antenna Interface 12 volt regulated power supply is passive? And if so where to find an appropriate scheme? Thanks. Sorry for my bad English.

Salvo.

Andrew,
Without knowing the exact circuit and components that you are using, it is difficult to be helpful but here are my comments. As I understand what you've described, if you put an inductor from the FET gate circuit to ground you have created a low pass filter and/or have added and shifted the poles and zeros such that the system may no longer be as flat as before. As you are aware, smaller bandwidth means less noise and lower NF. There may even be some parasitic resonances. Have you modeled the circuit in Spice and run a bode plot?? Have you performed an S21 plot with a VNA?

Agree with Rick, the J309 fet intrinsically has extremely low gate current hence high impedance ...having modeled and built bunches of J309 circuits for RF input amps over the years, there is very little difference in having a 1K "match" or a 1Meg "match". Also, if you are using a less than optimum test set-up on the bench, such as test leads and probes that create current loops, the test setup would be picking up E or H field noise or the probe circuit can become resonant or have increased Q. If you are using coax with connectors, the coax will have parasitic and harmonic resonances that will affect the reading in conjunction with the added inductor.

A 9dB Norton amplifier in the Antenna Interface was used to ensure that the total gain was approx. 10dB higher than the Excalibur NF. Thus to ensure that the higher amplifier gain would mask the receiver NF affecting the measurements. A 20uH inductor was used to simulate the loop’s reactance. The NF was measured using the gain method i.e. the excess noise above the amplifier gain when the input is terminated with a resistor. The negative NF is measured with a inductance connected to the amplifier input. Both ALA100s have an approx. 50 Ohm resistive input z as determined using an Array Solutions AIM 4170C Antenna Analyser. WinRadio Excalibur set 1kHz BW and the S Meter to RMS AVG. -144dBm is used as reference for the 1kHz BW The negative NF is defined as the amplifier noise being less than

the increase in noise due to the amplifier gain. Test results. Old ALA100 1MHz gain = 27dB (18dB with Passive Interface)Noise with 50 Ohm input = −116dBmNF = 1.0dB Noise with 20uH input = −118dBm (-127dBm with Passive Interface)NF = −1dB. New ALA100LN 1MHz gain = 28dB (19dB with Passive Interface)Noise with 50 Ohm input = −116dBmNF = 0.0dBNoise with 20uH input = −124dBm (-133dBm with Passive Interface)NF = −8dB. 3 other ALA100LNs were tested, the worst case was a -6dB NF. Looking at the above one can see that there is only a 1dB difference in the gain and NF of the two Head amps with a 50 Ohm input. The apparent -1dB NF of the ALA100 with the 20uH input is probably due to the fact that Inductors are noiseless compared to a 50 Ohm resistor. However, what is striking, is the apparent high negative NF of the ALA100LN. My first thoughts were when this showed up, that the gain had dropped by 8dB because of the loop inductance and this would show up as low antenna gain. However, the on air comparison suggested that this wasn't the case. Also Dave Aichelman ran some comparative tests confirming my observations. I do not have an explanation yet as to why the ALA100LN has an apparent negative NF or why the noise floor drops by 8dB, but it certainly accounts as to why some users are seeing improved performance. The theoretical NF of the ALA100LN is close to 0dB. One could speculate that there is a significant mismatch of the antenna noise from its real and radiation resistance being a small fraction of the amplifier input z. However, I have only been able to achieve a significant negative NF using JFETS. The ALA100LN uses 8 x J309 Fets. with noiseless feedback.The negative NF can be increased to approx. -10dB by altering the feedback and increasing the amplifier gain. Also the negative NF increases by a couple of dB where the loop inductance is higher e.g. a 20m circumference thin wire loop (30uH). Also the negative NF is maintained as the frequency rises. The ALA100LN has a sister, “Florence” the FLG100LN with an input matching/isolation transformer of 1152 Ohms for Terminated loop antennas e.g. Flag and KAZ. However, the antenna termination resistance makes the negative NF feature unrealisable. One may ask what is the significance of the amplifier having a negative noise figure of -8dB?It basically means, that there is the potential of an 11dB s/n improvement when compared to a conventional amplifier of the same gain and NF of say 3dB with a similar loop size. This feature could be used to compensate for any mismatch loss over wide bandwidths. Additionally the negative noise figure could compensate for usual NF degradation when loops are run as close spaced Phase Arrays. I am currently exploring to see if the apparent negative NF can be exploited with smaller loops. To this end I have extended the bandwidth of the ALA100LN from 10MHz to 30MHz by configuring the FETs to run in cascode with two Bipolar devices. However, there may be a bandwidth limitation due to the fixed input impedance of the amplifier compared to the ALA1530 with its loop/amp. impedance tracking verses frequency. 73 Andrew Ikin

<Without knowing the exact circuit and components that you are using, it is difficult to be helpful but here are my comments. As I understand what you've described, if you put an inductor from the FET gate circuit to ground you have created a low pass filter and/or have added and shifted the poles and zeros such that the system may no longer be as flat as before. As you are aware, smaller bandwidth means less noise and lower NF. There may even be some parasitic resonances. Have you modeled the circuit in Spice and run a bode plot?? Have you performed an S21 plot with a VNA?

Agree with Rick, the J309 fet intrinsically has extremely low gate current hence high impedance ...having modeled and built bunches of J309 circuits for RF input amps over the years, there is very little difference in having a 1K "match" or a 1Meg "match". Also, if you are using a less than optimum test set-up on the bench, such as test leads and probes that create current loops, the test setup would be picking up E or H field noise or the probe circuit can become resonant or have increased Q. If you are using coax with connectors, the coax will have parasitic and harmonic resonances that will affect the reading in conjunction with the added inductor.>

Alex, The ALA100 is a single stage push-pull amp., each transistor is 4 J309s in parallel, the gate and source are transformer coupled to provide low input z. Additionally the gate/source coupling dynamically reduces the source impedance from its static value of 16 Ohm to approx. 1 Ohm. This I believe has a dramatic effect in reducing the NF. The downside to this design is reduced HF gain as a result of the transistor Miller capacitance. Hence, the requirement to add a cascode stage using a pair of 2N4401s in a common base configuration. This also improves the OIP3. Other issues, the gain spread of the J309 means that devices have to be selected in order to secure a +80dBm OIP2.

Normally with fets one needs a high input z >1k to the gate to secure low noise. Which makes them not really suitable for low impedance wideband loops. The above design gets round this problem.

In this past week, the J309s have been replaced with much higher gain devices with a tighter gain spread. This results in a 2dB gain increase and lower IMD at MF; OIP2 +90dBm and OIP3 +49dBm.

Well, Andrew gave all the important info to reproduce the circuit. Details like biasing and power splitting can be easily figured out.
I am surprised that FET input devices yield such good results. There are BJTs that have significantly better voltage noise parameter. FETs have lower current noise, but it is not a factor in the low input impedance application.

As for the NF measurement, this metrics is defined for Z=50 Ohm systems, and extending it to inductive impedance only creates confusion (or possibilities for "creative" advertizing :)). Gain and NF are pretty much meaningless for loop antenna systems and have to be replaced with different parameters, reflecting the combination of the loop and the amplifier. Gain is replaced with antenna factor Ka (or effective height h), and NF is replaced with input noise expressed in field strength: Nfloor = Vnout * Ka in [uV/m] .

Chavdar LZ1AQ has good analysis of loop antenna systems on his site.

This makes sense to me.

The gain and nf have to be measured consistently. Measuring the gain in a 50 ohm system and the noise with an inductor will definitely give the odd results.

Kevin

Mike, I have been working with wideband loops for 20 years now using both JFET and BJTs. JFets have always provided a lower NF, but until recently I have only been able to match the IMD performance of Bipolars. I agree that extending NF to inductive z may not be valid, but there is no reason why the amplifier noise floor shouldn’t be stated when terminated with a inductive loop, as this represents its actual use. Gain and NF are important as well as the loop/amp. mismatch with variance in frequency.
The point I am tying to make is that you can have amplifiers that have nearly identical NF and gain in a 50 Ohm system or other impedances, but the JFET one has a much lower noise floor when inductively terminated. Hence, this would provide a more sensitive antenna with the same A F.
Replacing gain with Antenna Factor is all very well for large multi-national companies that have large budgets for antenna calibration and other measurements requiring screened rooms. But for small firms like Wellbrook this cost is out of the question except for the most popular loop; the ALA1530.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11094. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-07-01 13:15:25 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11094

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

"
FYI - just about finished the PCB design for the controller - double sided, plated thru' holes, silk screen and solder resist on both sides.
Mostly leaded thru' hole parts for ease of assembly with only surface mount parts for the RF detectors.
Self contained PCB to drive two steppers and LCD etc , just needs an external directional coupler.

One stepper drives the VVC and the second stepper turns the input loop thru' up to 90 degrees to optimize coupling and match.

I expect to be placing an order for a batch of PCBs very shortly and was wondering if you and or others in the yahoo group would like one ?

I don't know about cost but as the board is approx 4" x 5" it should be too expensive - I would expect £20 maybe less if I order 10 -20 units.

73 Tim G4WIM.
please let me know and I will pass on to Tim

11096. MFJ 1786 High SWR

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-07-21 17:38:32 UTC
From: fifteenmedium@...
Topic: 11096 Message: 11096

Hi Everyone,
I hope you can help me here. I just bought a second hand MFJ 1786 and can't get the SWR below 3:1 on any band below 15m. It is located on a 10th small balcony. I've looked under the hood and all looks fine and it seems to be working fine. I've reshaped the feed loop, squishing it seems to drop the SWR a bit.

I assume the building is coupling with it but I've looked around the web and seen pictures of these loops in small spaces, close to structure or even indoors and their owners are happy. My building is brick & concrete, the balcony railing is glass, the railing is metal. I can manage about 4 feet of clearance to the walls and elevate it horizontally about a foot above the railing. Still unusable for transmit.

Are they any ways to reduce the SWR? Would changing the feed loop size help? Changing the feed to a gamma match or another type?

Thanks for your input.
73's de Paul VA3ZC in ham radio hell.

This may be one of those cases where Walt Maxwell's saying, "Too low a(n) SWR can kill you", applies.

An SWR of 3:1 isn't bad. It's not perfect, you won't win any Nobel Prizes with it, but it ain't bad either and you can surely operate with it. At 3:1, the SWR loss is 1.2 dB, or one fifth of an S-unit. Would you notice that?

The only thing is, is your transceiver too picky about SWR? THEN it could be a problem.

And you didn't say how much worse than 3:1 it was on some bands.

But if you want to persist, move it away from the balcony and try it somewhere else. Bring it into the open. Bring it indoors. Re-orient it in the balcony. All these things could affect its SWR somewhat. I'm not saying it solves the problem, but it might.

If your building is concrete and brick, except for the balcony which is a metal frame, then it seems odd in a way that you would want an antenna smack in the middle of the one thing that is metallic, the one worst place for it. I understand the desire to have it away from inhabitants, for their safety. But an antenna doesn't need to be outdoors if the building itself is relatively transparent to RF. It's not like the antenna needs to breathe fresh air. Just because everyone else puts their compact loop in a balcony, doesn't mean you have to. Unless, that is, the building has a steel frame or a lot of Rebar.

Keep in mind, however ... I do not have one of these antennas. I am just speaking on principle.

Of course you probably want to know why your antenna doesn't tune to a lower SWR, or even better, how to change it so it can. I can't say. I *think* it has just the one tuning capacitor. Impedance is two dimensional (mag/phase), so you really need two degrees of freedom = two things to adjust, to be sure you can get the SWR arbitrarily low. By putting it close to your particular metal balcony, in a particular orientation, it might have altered the impedance in a way that the single tuning capacitor cannot compensate for it. Changing the feedloop size *might* help. Changing to a gamma match changes everything, it would be like starting over.

A few weeks ago I saw a youtube video where someone took his MFJ loop apart and found a dead bug in it, which was causing it not to tune up right. It took him quite a while to locate the critter once he had it open.

Regards,
Andy

Hi Andy,
Thanks for the great reply. I've never thought about 3:1 as down a fifth of an S unit. I'm used to flat or close to flat and start to panic when the needle moves up. The rig is a Yaesu FTdx 1200, fairly sturdy but am I shortening the finals lifespan with an SWR above 2:1? I think I read somewhere that an external tuner cannot be used with the 1786.

The 1786 has a coil at the feed loop. The manual says that you can stretch it or compress it to adjust swr but I'm not sure of it's purpose or which way I should be going. Also steretched and compressed the feed loop itself.

As for my building, it is a reinforced concrete, brick clad structure. Only the strongest HF signals get indoors. I need to get that antenna outside. I'd be pretty happy if I could get the SWR closer to 2:1.

Cheers.
Paul

"I never quite regarded hardware as buggy!"

Did you know where the term computer "bug" comes from?

The original computer "bugs" were actual bugs (moths) found inside the relays of one of the earliest computers, the Harvard Mark II. Rear Admiral Grace Hopper (one of the developers of COBOL) is credited with first using the term for computers. In those early days, things like relays and switches and patch panels were part of the "programming" that made the computers work. It wasn't until later that they started using stored programs that resided in memory.

Grace Hooper also came up with "debugging". Sometimes it literally meant pulling dead moths out of the hardware.

Andy

Paul,

I'm not an expert on this, so take whatever I say with a big grain of salt.

"... am I shortening the finals lifespan with an SWR above 2:1?"

I don't think there is such a thing as shortening the finals. They aren't tubes (right?), and transistors shouldn't wear out unless significantly abused, and when they do go it tends to be catastrophic, as in, broken within a few milliseconds. Semiconductors can sometimes suffer slow damage, but it is not common. A well designed transceiver should protect itself and there should be no damage. But sometimes the "protect itself" is in the form of limiting the power as the SWR goes up.

"I think I read somewhere that an external tuner cannot be used with the 1786."

I'm sure that you can. (Well, OK, not 100.0% certain, but I can't think of a reason why you couldn't use one.) It's not always the best idea, because adding an antenna tuner adds a little more loss into the system, but it hopefully is small. You just don't want to rely on the antenna tuner to fix an awful SWR from this antenna when the antenna itself is way out of tune.

I don't see anything wrong with using the rig's internal antenna tuner to take care of that last bit of "flattening" of the SWR.

In tube days you wouldn't care what the SWR was; you would have tuned the finals. That's pretty much the same thing as using the antenna tuner.

"As for my building, it is a reinforced concrete ..."

Ah-ha. Reinforced. That means Rebar. You do need to get the antenna out of that "cage". The balcony is only partly better because it is probably half a cage.

Regards,
Andy

11102. Re: MFJ 1786 High SWR

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-07-22 13:13:45 UTC
From: georgec@...
Topic: 11096 Message: 11102

Paul, are you certain that the antenna is tuning when you push the up/down buttons on the control box? Can you hear the receiver noise level peak at some point in tuning it? The antenna's capacitor may not be moving, no tuning, high vswr. This type of antenna will not work with a conventional tuner. The antenna itself must be resonant at the operating frequency to perform at all. If the antenna is say, 20 khz or more off resonance its performance is horrible. Tuning the line with an external tuner or whats in the rig simply turns it all into a dummy load.

So you need to verify that the capacitor is tuning when you press up or down on the control box.

How does it perform on 15 and above? Can you tune it there? If it does tune with your symptoms I'd look for a mechanical block on the capacitor's movement as it goes to increase capacity.

Just some thoughts after using a loop for a long time.

GeorgeC

Topic: 11096 Message: 11103

Hi George,
Thanks for your input. I've had it apart and can verify that the cap is moving.

I've been doing some experimenting with the placement on the balcony. Today I have it tight against the brick/glass wall and as far as possible from the railing. The SWR has dropped to as acceptable 2:1.I'm on wspr at the moment getting pretty reports running 10 watts. E50W in the North Cook Islands is reporting an SNR of -25db. Not very strong but not bad for 9,770 km.

I need to do more experimentation to find the optimum position but I am becoming a believer in this loop.

Thanks!
Paul VA3ZC

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11105. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-08-01 13:01:55 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11105

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

11106. Mounting Vacuum Variable Capacitors on Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-08-16 03:29:52 UTC
From: N7RJN@...
Topic: 11106 Message: 11106

Does anyone have any suggestions on physically mounting variable vacuum capacitors on a magnetic loop antenna? I have a Jennings UCFS-250-15S capacitor the includes the FM2 and FM2B flanges, but it is not clear what the best way is to mount the capacitor and connect to a copper loop. Photos of installation would be appreciated.

73,

Bob

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

This again? Check a real world long-term user of the RF Pro-1a antenna, like me (I am 'JRT3' of eHam's reviews.). I bought both a Pro-1a and a Palstar R30A when the latter had just replaced the earlier R30 model - some 6.5+ years ago. I was attempting to restart my longtime SWL/DXer hobby, which had started at my former house with my 150 ft long wire antenna, which I had erected in 1976. Bothered from day one by aperiodic powerline noise, always traced to the pole in front of my home - and the high tension feeds to my subdivision, repeated calls to AL Power Co. offered no improvements. Over the years, many antennas were tried, including dipoles, slopers, & TTFD. All eventually were abandoned, many because my tree supports died. Then, along came the Pro-1a - mounted on a five foot mast from my back deck's apron, it would effectively null the noise source from in front of my house! I had good listening for a while - then the deadly 1/2012 tornado hit.

I was spared a direct hit, although my neighbors on the next block - and the subdivision's power poles - weren't so lucky. My deck furniture and eave hung wind chimes, along with some roof tiles were my only casualties. My Pro-1a had worked loose from it's mount and wound it's RG-6QS around the mast. I loosened it's mount and unwound the cable - the antenna worked fine, once power was restored - except for the 'new' EMI sources APC left me with - the Pro-1a can only null one directional source at a time - oddly, the one in front of my home was still the strongest. A year and a half later, we had enough of our old neighborhood - and moved to a garden home with an HOA - and no outside antennas allowed. I bought a tripod mast base and carried it and the antenna up the stairs to my tall/steep-roofed attic, placing it in a clear spot and connected it via a "F" connector female-female splice to a line emanating behind my desk. A jumper to the wall connector and I was ready to listen. I replaced CFLs with 6W LEDs and dimmers with switches, leaving me with a fantastic listening site.

The Wellbrook is a great antenna - but it's sealed plastic construction and use of instrument connectors (BNC) has always been cause for concern here. In contrast, the Pro-1a, like the earlier and later variants, is modular, all metal, and uses outdoor rated RG-6 (Quad Shield) cable and easily weather-proofed type F connectors. I bought the crimper tool and a handful of connectors from a local electronics jobber for <$25. The type F male to BNC female adapter needed to make a BNC cable fit the power inserter's output can be easily found - and a BNC/RG-58 cable, with it's sometimes 80% shield (RG-6QS is 100%!), can be used to connect the receiver. I like the Pro-1a, in case you are wondering. And, it's American designed and made.

John

The review you cited below is amateurish, at best. No scientific conclusion can be drawn from this "review". There were far to many "other" variables that were not accounted for, making it impossible to draw the conclusion that one antenna is better than the other.

Further information, that is based on sound engineering and test methodologies, is available on the web that compares these loops

Ah, "amateurish", indeed! High praise for reviews which had no CV requirement for their posting. If you want a level of professionalism, I'd suggest you look elsewhere - it would seem obvious to me that eHam and a Yahoo! group would just reek of "amateurism", as they are hobby endeavors. My posting was meant to convey my satisfaction with a product I've enjoyed owning and using for over 6.5 years, ie, it's not just something I found compared at a manufacturer's site. Additionally, the eHam review was a follow up to my earlier such post. Apparently they now delete previous posts from the same source.

Oh... what kind of range is "far to many"?

John

John,

Thanks for posting the article. I purchased a Wellbrook ALA-1530 loop about two years ago to use for my “diversity” receive site with my Elecraft K3 transceiver. I have been very pleased with its performance.

So sad that some people have to comment the way they do. You were simply sharing something that you felt others might find useful.

Just just go listen to different sdr webservers and form your own opinion. My conclusion was that more signals could be heard with the ALA1530 loops compared to the Pixel pro models. What you hear is what you get! You can measure as much as you want but the (live) end result is what counts for me. Mind you there are others like the HDLA models that are also working nice in the same league as the discussed loops.

Ron,

Your methodology does not follow sound engineering practices. Your suggestion leaves so many uncontrolled parameters unaccounted for, allowing you to draw any conclusion you want to draw. Since you are only comparing two antennas, and using your test platform, you would do **just** as good by taking a coin and flipping it in the air. Heads would "prove" the ALA is better, tails would "prove" the Pixel is better. It sounds like your coin flip came up heads.

Yes Robert..Indeed a nerve has been struck. I was just sharing some info for others to possibly enjoy.
Believe it if you want or not-that is ok.

I personally refuse to get into a spat with such....

I also see the Elecraft fan's who get quite defensive if someone make a comment or reference regarding that gear.

When someone spends lots of money on a piece of equipment regardless of its true performance they are inclined to defend the heck out of it!

Having also the chance to do some A-B testing indeed the Wellbrook out performed the Pixel...Scientific..No..but who cares it was me all about which one performed better in my personal application.

Enjoy your Wellbrook, I sure do. And the customer service I have received from Andrew has been far superior to some other "made in US" gear I have experienced....

In closing my post was only meant to share and enjoy with those who shared similar interest...not to create issues or upset others.

Geeze I now see why there is not much activity on these groups.

With Kind Regards....

I think you are taking the responses in the wrong manner.

I would much rather have a fact based, scientific review of a product that is based on engineering principles.

The URL you mentioned in your post is a review that is NOT repeatable and would not withstand a peer review. My intent was to point that out. It had nothing to do with monies spent nor customer support.

Enjoy your Wellbrook.

11121. RE: [loopantennas] Wellbrook ALA-1530 vs Pixel RF PRO-1A

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-09-06 22:47:39 UTC
From: Fredric J. Einstein
Topic: 11110 Message: 11121

I purchased a Wellbrook ALA-1530 about 10 years ago when I was living in the Detroit area and found it unfortunately to be totally deaf. I also had a Cushcraft vertical antenna which worked wonderfully for both SWL'ing and ham radio work. The owner of Wellbrook, Mr. Iken worked with me (sending me replacement loops and control boxes) and eventually refunded the purchase price (although I was "out" the very expensive shipping costs back-and-forth to the U.K.) when the problems with the antenna in my particular location couldn't be solved. My location may have been the problem. I lived about a city block away from 5 very powerful FM broadcast towers in one of the near-northern suburbs of Detroit. My vertical, even in the close proximity to these FM stations, was always able to perform very well on all bands from AM broadcast to 10 meters, but the Wellbrook, as I said, was totally deaf in my location. No signal, even on strong local AM stations and totally silent on the shortwave bands.

I'm wondering if any of the "loop experts" on this mailing list might be able to venture a guess as to why I had such bad luck with the Wellbrook, which had wonderful reviews and is obviously a great performer in most circumstances. Did the close proximity to the FM broadcast stations have anything to do with it?

11122. Any obvious errors in this loop design?

Hi Group,
I thought that I would build my ultimate AM/LW loop antenna and I am hoping that the group could offer me any advice if I am going seriously wrong.
I started with the maximum size loop that I could physically handle by myself and came up with a square loop with 7 foot sides (10 foot diagonals) mounted in a diamond orientation. Timber construction.At each apex, I plan a "spreader" 3 feet long at right angles to the diagonals.For wire, the plan is to use the outer braid of 75Ohm TV coax - 8 turns wound on the spreaders. This gives a turn spacing of about 4 inches and a conductor diameter of about 4-6mm.
The whole shebang will be remotely tuned using varactors and buffered via a FET balanced amplifier with cat6 cable providing the power, tuning and switching voltages. The cat6 might also provide an unbalanced signal path down one of the twisted pairs or balanced down split pairs depending on how many conductors are spare after the power, tuning and switching.
I have not found a loop calculator that can confidently handle a loop this size and so am flying blind in regards to predicted performance.
Loop inductance is not a problem because I can adapt the varactor tuner to suit. Stray capacitance is a problem due to its effect on the upper end of the tuning range and I would like to minimise the amount of band switching by keeping the stray capacitance to a minimum.
The loop will be erected in a suburban environment with pole-mounted mains supply, a nearby plasma TV, and under the training path of a busy light-aircraft airfield.
Does the design have any glaring errors? Can anyone see a simple way to improve its performance without increasing the loop size or costing lotsaloot?

Thanx in advance,
Ray

I have built some very similar...10 foot diameter octagonal loop (6 turns spiral wound) and varactor tuned. It was made for the AM broadcast band. It works great but when the varactors are tuned precisely on a station, the antenna re radiates some of the signal and it is picked up by the cat5 cable that supplies the varactors. The result is that the antenna detunes in accordance with the received signal and the sound is raspy. I have to tune the antenna slightly off resonance and this clears up. Soooo the advice I would give you us to use shielded cat 6 for supplying the varactors.

Good luck and keep us posted how it works out. Steve VE9SF

A preamp for AM BCB makes no sense with a 28 foot
perimeter loop, considering the very strong signals
on every channel. Here is a design for a remote
varactor tuned loop that uses coax for feedline
and runs the varactor DC over the coax:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

Although the article describes a version for 160 and 80
meters, it is simple to add more varactors to cover the
AM BCB. No CAT6 is required. It uses just one turn.
Multiple turns are unnecessary.

This is a proven design; why reinvent the wheel?

Loops are used by AM broadcast band DXers mainly to rotate to null out a stronger signal to receive a weaker one on the same freq or to null out a powerhouse signal on an adjacent channel. For the ultimate rejection, the loop needs to tilt, not just rotate in a horizontal plane. That's not easy to do with really large loops.

If the aim of the loop is to null out a single interference source, I would suspect that if the noise source were close to the loop, the RF field might not be uniform and impinge unevenly on a large loop such that a small loop would have better nulling. That would make for an interesting field test to see if true.

If the goal is just to pick up a large signal, an active monopole antenna would be much easier to build.

I partially disagree. Yes, loops can null specific sources of noise or interference but they also reject a lot of noise that a monopole receives. A monopole is good for transmitting but no very good receiving.

Gentlemen,
I am blown away by the promptness and expertise of your replies. The design will be modified in accordance with advice received. The loop will now be tapped so that I can set the best conditions for my target frequencies. Having the ability to change the inductance will also make the tuner easier to operate -bonus. I am targeting 200KHz to 1710KHz and am looking for as much DX performance as I can get.
Advice re crosstalk in cat5/6 cables means that precautions can be taken at the outset instead of spending hours chasing a problem later. It looks like I will be spending some time on shielding and isolating.
I would love to make the loop tilt. In the corner of my mind is a screw jack and occy strap concoction that might, one day, do the job. Maybe I should look closer at what techniques back yard astronomers use to position their telescopes.
Now that what passes for winter here is over (well almost) I will brave the outside world and start construction today.

Thank you heaps for your input. I will put your posts into a special folder and use them as a reference volume.

Good article Rick...I am planing on building another loop and will base it on this design. However, instead of coax, I have lots of twenty foot 3/8 inch aluminum rods that I plan to use. I intend to use the outer conductor of RG-6 as the antenna inside of the aluminum rods. The main reason is for mechanical considerations, but it seems to me that the aluminum rod is more magnetically transparent than the braid of the coax. 73....Steve VE9SF

A 1 meter diameter loop is a very efficient FM broadcast band antenna. It's entirely possible that the FM signals saturated the input stage of the loop amplifier, although this normally evidenced by intermodulation products seen in the 0-30 MHz range rather than loss of sensitivity.

The Pixel Pro-1 amplifier I designed includes an FM broadcast reject filter for this reason. Likewise, my Z1501F active voltage probe antenna includes input FM band filtering.

You must have lived around the Southfield / Detroit border.

I don't know how your DC control is wired, but it's probably RF bypassed at
both ends, isn't it?
So I wonder how this feedback loop works to detune the loop, unless maybe
the control wiring
is very long? Or is the RF takeoff sharing the same Cat5 ? I have not built
a loop, but I think
I would use twinax or doubled coax for the RF takeoff.

Its a pleasure to share what little I know and to learn from others in the group. You wanted an idea on how to tilt the loop, so I will show you what I did. See attached pic.

I had a big C band dish which I removed from the polar mount. In it's place, I fastened a sheet of plywood on the mount where the dish used to be. To this plywood base, I mounted two small dishes, one linear and one circular. Also to this base I mounted my big loop. Now when I power the actuator the two dishes follow the satellite arc and the big loop turns and tilts at the same time.

You might not want to go through all this trouble but you could put up a stationary tilted loop using a C band polar mount...lots of folks give them away just to get rid of them.

I am curious to know if anybody else has ever done this....Regards.....Steve VE9SF

Hi,

Sorry for the belated answer. I don't know the capacitor size, I just got the antenna last week.

Regarding usefulness, I haven't tried on 7 MHz yet. It was challenging to tune because of my poor environment.

If the propagation allows I will try this weekend and let you know the result. But remember that my antenna is indoors, at the first floor and surrounded by buildings. I am only operating JT digital modes.

Just thought you guys would like to take a look at this video of my mag loop tuner based on the TF3LJ power meter design but with extra HW and firmware to make it tune anywhere from 3.7MHz to 14.5MHz and achieve a VSWR of 1.05 (yes I do mean 1.05) in a matter of seconds.

The design will be published by the RSGB shortly.

73 Tim G4WIM / KT6UK

PS I've recently been told the name MagLoop is trade marked - so just for the avoidance of confusion this design has nothing to do with MagLoop

I'm puzzling over the best design for a remotely tuned, large Stormwise ferrite loopstick. I have built a "regular" sized version with a common balanced FET amp. It works well but I want to supersize the iron. Which design is best and why? I am especially curious about the advantages/disadvantages of feeding the tank circuit directly into a very high impedance FET input as opposed using a separate winding. to If using a separate winding, can you recommend a build-able amp that would be a good match for both the input impedance and a 50 ohm output. Or perhaps details on winding a passive matching xfrmer. What type torroid, how many turns etc. I'm a not so great original rf designer but I'm really good at reproducing successful designs and learning from them!

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Shielded-Loop Receiving Antenna by N5FC
Shielded-Loop antennas have some nice properties that make them desirable as portable receiving antennas.
http://www.io.com/~n5fc/loop_ant.html

Antique Electronic Supply
A sorts of older variable tuning capacitors for your loop antenna that needs one bad.
http://www.tubesandmore.com

Fair Radio Sales
A wide variety of electronic components, radios, and variable capacitors for your loop antenna
http://www.fairradio.com/

Ocean State Electronics
Rhode Island's best selection for a wide variety of the best tuning capacitors for reasonable price, tell them that electronicdx (Adam Ebel) sent you.
http://www.oselectronics.com/ose_p96.htm

The Crystal Set Society
Here are some capacitor available from a club that devotes to Crystal Set Radio
http://www.midnightscience.com/catalog5.html

The Surplus Sales of Nebraska
This surplus store based in the state of Nebraska, has the one you might need, but they have minumim order policy
http://www.surplussales.com/Variables/AirVariables/AirVar1.html

Dan Small Parts and Kits
Dan's wide selection from Canada.
http://www.danssmallpartsandkits.net/

American Science and Surplus
A big spool of wire here just about for AM

http://www.sciplus.com/category.cfm?subsection=15&category=150

DigiKey.com
For ribbon cable and other sorts of wire.
http://www.digikey.com

Femco Magnet Wire
Femco Magnet Wire is a joint venture company that has been supplying round insulated copper magnet (winding) wire to the transplant market since 1988.
http://www.femcomagnetwire.com/

Litz-Wire,com
Welcome to Litz-Wire.com!
http://www.litz-wire.com/

MCM electronics
They do sell wire and magnet wire here
http://www.mcmelectronics.com

MWS Industries
A place for all sorts of wire for business and industry
http://www.mwswire.com

Magnet Wire from Radio Shack
This is what I use often
http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F011%5F010%5F004%5F000&product%5Fid=278%2D1345

Mouser Electronics
Mouser has the biggest spools here for a great price, that makes sense
http://www.mouser.com

Ocean State Electronics
magnet wire at a good price
http://www.oselectronics.com

WIRE "Flex-Weave" Antenna Wire
"Flex-Weave" is a hybrid aerial wire that consists of 168 strands of woven #36 solid copper wires that provide high strength and extreme flexibility. The most popular version of "Flex-Weave" is the 'equivalent' of #14 AWG wire size. It can be 'used' for unsupported spans up to 200 ft (100-150 ft in areas with high ice and wind loading).
http://www.radio-ware.com/products/fw.htm

WIRE "QuietFlex" Antenna Wire by Antennas & More: Insulated, Strong, Flexible and Durable
"QuietFlex" Antenna Wire by Antennas & More: "QuietFlex" #14 AWG Wire has more than 41 Strands tightly twisted together under its Flexible Insulation making it both Strong, Flexible and Durable.
http://www.antennasmore.com/wire&.htm

11143. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-10-01 13:22:34 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11143

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Tracey - is it possible you got hacked?

As a reminder to all my fellow group members - it is extremely dangerous to follow a link to an unknown website. Doing so may infect your computer with malware. Although I have heard of no cases where malware has been transmitted through Yahoo groups - this could well be a hacker gaining control of Tracey's account. Don't follow the link!

This is a Yahoo group which operates as a mailing list. No one needs to be hacked or virus infected. Any email that is sent to the list with a return address matching one of the users will be posted to the group. Spoofing the return address is very easy. That is one of the weaknesses that we are exposed to with a mailing list like this. Anyone with a valid email address can post anything they wish.

11149. For Sale a MW and LW 1 Meter loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-10-05 21:05:30 UTC
From: everettsharp@...
Topic: 11149 Message: 11149

I have two 1 Meter Loop Antennas for sale, one covers the MW band and the other covers the LW band. I am asking $200 for the MW loop and $225 for the LW loop. I do not want to ship them so they are only available for pick up at my QTH, which is Tuscaloosa, AL. They are one of a kind and very professionally built.

There is an article in the files section, "The Twin Hex Loop Antennas" that has pictures and info on the two loops. If there is interest please contact me off list at everettsharp (at) aol.

Attachments: 2 described; binary payloads are missing from this source WARC

Hi Folks, I'm a newby novice looking for some ideas for a new HF Mag Loop. I've built up a timber frame to support a loop with a diameter of 1200mm. enclosed attachment Exel calculations and the type of capacitor that will be used.

I'm unsure to which diameter pipe to use the calculations are for 19mm but would like to know from any of you that have been building loops for HF RX/TX which you found to be the best?

I was thinking about contacting someone local who does steel fabrications to see if i could have solid 20mm copper rod curved to a perfect circle with the meeting gap at the top which ends of the rod would be made flat to make straps for either air spaced capacitor or vacuum cap.

would having solid rod all the way through gain me much,? there are losses when using copper pipe if I was to choose an oct or hex design, losses at each joint.

Advise Advise Advise please from any of you PRO builders.. would be very grateful

Hi,

Solid copper is total waste.

Skin effect means that only the outer conducts. Hence only tube needed
and even it walls probably thicker than conductive depth.

The excess weight and COST is not needed, see above for reason.

Cheers,
Will

Hi Lee,

A number of us are going to do TP DX next week along the Oregon cliffs for enhanced reception. Guy Atkins and I will be bringing 1530's along. His will be the new LN Pro version, so there should be a nice report on the IRCA website in a week or two after that. If I can find a spot, I might try phasing 2 1530's for a narrower pattern. You still need 65' to 130' separation to get decent gain, so I may not find enough room for that test.

Hi Lee,

As my pal Dave mentioned I'll indeed be using the new ALA1530LN Pro antenna next week on our DXing trip (10/23-10/26). I will also have the other Wellbrook antenna in the Imperium line up, the ALA1530S+ Imperium for comparisons.

Based on my prior experience at this location on the Oregon coast https://www.google.com/maps/@45.7437814,-123.9586501,3a,75y,135.83h,78.18t/data=!3m6!1e1!3m4!1sOEZ9zEy1PKc8fvNo9rV_sg!2e0!7i13312!8i6656!6m1!1e1, even compact antennas can experience significant sea gain. The altitude over the Pacific is approximately 450 feet. Pacific NW DXers like to head to these cliffs for the excellent medium wave reception from New Zealand in the summers, and Japan/China/Korea/etc. this time of year. We park at the Highway 101 turnouts a couple hours before dawn, and start recording the band with our SDR receivers.

Wellbrook's 1-m. compact active loops are excellent for these limited space DXing spots. For those willing to bring along some portable masts and bases, you can use Wellbrook ALA100LN or FLG100LN modules for smallish (~10 X 15 ft.) rectangular loops or Flag antennas.

I'll report back with some comments on the antenna performance after the DXpedition. BTW, if you haven't read my ALA1530 review http://www.dxing.info/equipment/ALA1530-vs-RFPRO-1AReview.pdf from a few years back you may want to check it out.

Hi Guy..

Yes I did read your review and found the Wellbrook/Pixel comparison interesting...
I need to compare a "Lazy L" as I have to remove it, courtesy of the local council..

I have a magnetic loop `tho it`s not wide band enough, but may have to resort to using it... the cap is twin gang series coupled but may have to switch to parallel coupling to gain extra R/X bandwidth - much easier to get a Wellbrook !!

I `could` use the Wellbrook pre-amp and re-configure the "Lazy L" back to a EWE or Flag, if the council would allow it (maybe disguise it as a clothes drying line complete with clothes pegs..hi)

My receiver is a Winradio G305i sdr !

Looking forward to your report altho` I live in the West Midlands (Birmingham) not the wind swept cliffs of the coast hi hi...

Regards.

Thanks Lee.

The group page that you linked to indicates that it's necessary to join, but provides no Join button. Please consider adding some instructions to help people join.

For others who are lost, I can tell you that generally you must use the Search Groups function and then click Join Group in the group's description.

Like so many user interfaces these days, Yahoo! Groups is quite baffling. Inconsistent, too. Sometimes it refuses to do something because "You need to be a member to perform this action," even though I'm logged in! And on repeated logins this morning I find that MagLoop sometimes appears in the Groups Home list, but sometimes doesn't. But if I find the group through a search, it then appears in the list again. Still can't read anything. Perhaps I'm awaiting membership approval. Not sure. No membership status is displayed that I can see...

Would emailing magloop-subscribe@yahoogroups.com <mailto:magloop-subscribe@yahoogroups.com> be a simpler way for people to join?

Looking forward to seeing more information about loop antennas.

I normally design and build Ultra low noise preamps for EME use, but I was asked about one for HF. I tackled the project and have come up with a design that is below 1dB NF and has a gain of 25dB from 1-150Mhz ... and actually usable from 300khz to 1.5Ghz. I made some extras if someone needs one....they are various types from 16dB gain to the 25dB ones.

If anyone wants a schematic please email me off list and I will send a copy. They are cheap to construct ....$60+/- complete depending on parts supply.

Hi Pete,
The most interesting parameter on HF is the strong signal handling (IP3).
In the loop antenna application, there is also a requirement of very low input impedance, not so much for matching as for realizing the deep null in the antenna system directivity pattern.
In other words, it is not amplifying the weak signal that we worry about on HF, but reducing interference from strong out of band signals or strong in band signals coming from another direction.

73, Mike AF7KR.

The data sheet I saw specs it down to 50 MHz. The reason for
choosing this spec is that the device technology is ephemt.
This technology has 1/f noise below that frequency, which
is why they spec it to only 50 MHz, as far as NF is concerned.
The device will "work" all the way down to whatever frequency
limitations are imposed by the user's coupling capacitor and
feed choke, but the low NF only applies above 50 MHz.

More bad news: those nice NXP MOSFET's that work great for
FM BCB and UHF TV tuners also have 1/f noise problems that
make them a poor choice for AM BCB and 160 meter preamps.

If anyone finds an exception to the above, please post it
to the group.

OTOH, there is no 1/f noise issue for JFETs at least down
to the AM BCB. Ditto for BJT's.

I don't have that, but I can suggest the Hittite (now owned
by Analog Devices) HMC-580:

http://www.analog.com/media/en/technical-documentation/data-sheets/hmc580st89.pdf

It comes in a package that dissipates heat well and is
breadboardable with a soldering iron and wire solder.

I made up a PC board for it and have some extra PCB's that I
will sell for $10 plus mailing (allow $2.00 in the USA).
The PCB has provisions for sending DC over the coax to
power the amp.

The low frequency response of this amp will be limited by
the DC feed inductor. I have been using it for 160 meters,
so you may need to change the feed inductor to go to MW and
below.

An interesting idea you could explore would be to make
a push pull amplifier using two HMC380's. The output
transformer would replace the feed choke for purposes
of DC feed. It should make a big improvement in 2nd
order intermod, of course. You need to make sure that
the transformers don't themselves have intermod that exceeds
what the amplifier produces. Therefore, you should make
transformers with "binocular" cores, as popularized by
W8JI (see his web site for info). BTW, you also need
to worry about intermod in the DC feed choke when using
a single HMC580. Do not use an closed core (IE no air
gap). This rules out the binocular core to build a
DC feed choke for a single amplifier.

Rick,
Is the MMIC device that mention below stable? I have played with some MMIC devices that tend to go into oscillation.

I have seen the same problem in other MMIC's. Some MMIC's are
very sensitive to an inductance in the ground lead, or resonances
caused by the PC board. This device has only 1 GHz bandwidth and
has a ground paddle allowing very low inductance to ground. If you're
really concerned, use the evaluation board from the vendor. It is a
bulletproof microwave quality board. My homebrew board is just for
HF and is nothing special.

In any event, I have never run into any oscillation problems with
the HMC580.

11179. Video Comparison of Wellbrook ALA1530LN Pro and ALA1530S+ Imperium Loop Antennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-10-28 07:29:19 UTC
From: dx@...
Topic: 11179 Message: 11179

This past weekend I found some interesting results from medium wave DXing with both models of Wellbrook Imperium loop antennas at the "fabled" Rockworks cliffs near Manzanita, Oregon USA. This location has become popular the last few years with Oregon, Washington, and British Columbia DXers due to the signal enhancement at this narrow strip of land approx. 150 meters above the Pacific ocean. The main benefit seems to be splatter reduction of "pest" stations due to the signal blockage of the rock walls blasted into the cliffs for the coastal highway 101. However, a boost of signals around local sunrise is also beneficial, and is a common occurrence near salt water beaches.

Because of the limited space along this scenic coastal highway, all antennas used for DXing need to be both compact and temporary. Wellbrook loops supported on pro-audio speaker stands are a great way to go, and can easily be set up in the pre-dawn darkness.

Please read the description as well as see the video at this YouTube link:

Long wire collects more signal, and may even have better S/N. But it doesn't have the deep null of the loop, so the "Signal to interfering signal" ratio is typically much worse. This is very important for AM DXing.

Date: 2015-10-30 12:30:46 UTC
From: leo1949uk@...
Topic: 11183 Message: 11183

I have ordered the Wellbrook ALA1530LNPro and expect it to arrive Wednesday hopefully...??
What is the best height to mount it ??1 metre magloops are reckoned to be best at one loop width high... as this Wellbrook ALA1530LNPro is mentioned in passing, as a magloop, does this mean at 1 metre off the ground too ??
My vertical homebrew 1 metre magloop works well at 1 metre height !!

Regards.

Lee G6ZSG.

Hello Lee,

the Wellbrook compact loops are very flexible when it comes to mounting height. Even folks who have place it right at ground level (due to severe siting restrictions or just temporary use) report surprisingly good results.

Andrew at Wellbrook has told me that 1-1/2 to 2 meters is perfectly satisfactory. I have only heard of infrequent issues when mounting these loops extremely high... above 5 meters for example. In a very high signal urban area, excess height could contribute to overloading (which is a rare occurrence with any Wellbrook product).

Hopefully Andrew will respond and give us some additional thoughts on height above ground.

Thankyou Guy..

2 metres- that is a rather convenient height as I have steel washing line posts that high ;o)
but I can eperiment also ! I can then return my "Lazy L" back to its original use namely, feeding my Yaesu FT817nd QRP... Looking forward to a response from Andrew !!

Regards.

Lee...G6ZSG.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11187. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-11-01 13:25:36 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11187

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Hello Lee,
the Wellbrook compact loops are very flexible when it comes to mounting height. Even folks who have place it right at ground level (due to severe siting restrictions or just temporary use) report surprisingly good results.
Andrew at Wellbrook has told me that 1-1/2 to 2 meters is perfectly satisfactory. I have only heard of infrequent issues when mounting these loops extremely high... above 5 meters for example. In a very high signal urban area, excess height could contribute to overloading (which is a rare occurrence with any Wellbrook product).
Hopefully Andrew will respond and give us some additional thoughts on height above ground.

The prevailing wisdom on small loop antennas is that because the circumference is less than 1/10th the wavelength, the current is pretty much equal around the loop. But I have seen videos of measurements that show they are directional with most of the signal coming from the point opposite the capacitor.
That means many small loop antennas are directing most of their energy into the ground!

Anyone here done a test of their loop directionality? Seen any evidence that this is not correct?

Small Tuned Loop Radiation Direction https://www.youtube.com/watch?v=NdofH6R22Dg

Hello Lee,

Your G8's sticky case is a very common problem with the Eton E1. The textured finish on these radios is an early and problem-prone formulation of "grippy" coatings, according to a chemical engineer that has posted some messages on the E1 Yahoo Group about the problem. What happens is that the coating breaks down prematurely and absorbs moisture from the air. It becomes sticky and never really recovers fully. The coating continues to disintegrate over time.

The solution is to fully remove the coating with a strong percentage of isopropyl alcohol, such as the 90% formulation. Note that the ~70% alcohol is NOT appropriate. Many E1 owners have laboriously scrubbed their receivers with the alcohol on a rag, but this is tedious and can result in scratches to the underlying plastic if you are not careful.

What I discovered is that if you fully remove the radio's knobs, PCB, and all internal parts you can submerse the case in a pan full of the alcohol, and the sticky goo begins to float off the plastic after 15 or 20 minutes. Then use a clean soft rag to remove any excess sticky mess. You will have to keep the rag wet with alcohol.

IMPORTANT! the clear plastic window on the radio's case will get foggy from the alcohol. You will need to restore its full clarity with plastic polish, preferably a multi-step cleaner. In the USA, Novus Plastic Polish is a popular choice.

The good thing is that the lettering on the radio is on the plastic itself, and will not come off with careful removal of the sticky finish. The textured coating is actually a clear spray onto the plastic during manufacture, although it turns slightly yellow with age.

The key point here is to avoid most of the scrubbing of the case by just soaking it in a pan of alcohol first. Let time and the submersion do most of the work for you.

I have seen demonstrations that show quite a bit more illumination of fluorescent bulbs, from around the vicinity of the tuning capacitor. I'm pretty sure that is because the *voltage* (not the current), and hence the E-field, is very non-constant around the small loop, and is maximum near the capacitor. But that is mostly if not entirely a "near field" effect --- which is to say, it is not a radiating field. It falls off after a short distance and doesn't contribute to radiation.

I have not seen any references that say the radiation might be stronger away from the capacitor end.

It is true that the current is *slightly* higher at the end opposite the capacitor (depending on loop size), but I think the difference can pretty much be ignored.

Anyway, I think it could be shown that a pair of incremental conductors, conducting slightly different current magnitudes, and separated by a meter or two, do not have any bias in radiation towards one side or the other. I don't have that in proof form; it just "feels" like it ought to be provable.

If you trust NEC simulations (and I'll admit there are good reasons why one might not), the radiation from a small round loop is for all practical purposes uniform in all directions, in the plane of the loop. I haven't tried a triangular loop yet.

Anything that is measured near a small loop, I would take with great suspicion. The near-field E and H fields do not relate directly to the far-field, and if one were to assume that a strong near-field means an equally strong far-field radiation, that would be incorrect.

Regards,
Andy

Have you looked at the videos I posted links to? One clearly shows different current around the loop and the other clearly shows directionality in the plane of the loop. When I say "clearly", I mean if the measurements were done correctly and I don't see any indication they were not done correctly.

I *never* trust simulations if they disagree with real world measurements and I don't care *who* wrote the simulations. A simulation is a mathematical expression of what you think is happening and if that is not well understood or not implemented properly, the simulation results will not be right.

I would like to discuss the videos. But if you don't look at them we can't discuss them.

Rick

"Have you looked at the videos I posted links to?"

When I first replied, no I hadn't yet, because I didn't see them. They looked to me like ads at the bottom of the message. At first, I stopped reading just above them.

I started watching the first video but was interrupted and ran out of time. However, it clearly is NOT a small loop. The video states that it is a 1/4 wavelength loop. That means it is half the size of an ordinary half-wavelength dipole, then bent into a triangle. Such a large loop definitely doesn't have the same current everywhere along the loop.

I still need to watch the videos. But I've seen a video demonstration before that claims to measure the current along the circumference, which is a measurement I would take with much skepticism, due to the extremely high voltages present. Making a current detector that is totally insensitive to voltage or electric field, is difficult to do. So some interaction is likely.

"A simulation is a mathematical expression of what you think is happening and if that is not well understood or not implemented properly, the simulation results will not be right."

Definitely true!

I completely missed that first part. Being a quarter wave antenna means it is *not* a small magnetic loop by definition. I have to assume the other video is the same way, operating at a much higher frequency than a small magloop would work with. That explains a *lot*. Thanks for catching this.

Rick

Now that I finally had time to watch both videos ...

I can't say if what he's saying is right or not. The first video uses what might be called a large-ish small loop; not a <1/10 wavelength loop. His webpage where he shows why the current is not uniform around the loop, uses the 1/4 wavelength loop to illustrate, and it makes sense to me, it is what I would have expected too (except that he says it's 50% at the ends, but I would call it 71% if it follows the sinusoidal distribution he shows). If you do the same thing with a 1/10 wavelength loop, the current is much more uniform (within about 5%) -- as most people claim it is.

On the other hand, his measurements with the homemade current probe seem to show a far bigger variation in current magnitude than his own theory predicts. What's up with that? I don't know. Maybe it's that interaction thing with the voltage and/or the E-field. In that video, he really is using a small (<1/10 wavelength) loop, where it "should" be more uniform.

I am uncertain about the first video. The triangular loop (yes the second one is circular) -- the size which is too large to be a "small loop" -- the fact that he is never really far-field (he barely crosses the "boundary" where near-field dominates), all make it slightly questionable. But his results seem very consistent.

The later shots in that video where he has a big van parked directly behind the antenna, are very suspicious. I would discount that part of the video.

"It is very hard to imagine no one has tested this in nearly 100 years of using magnetic loop antennas."

Let's think about that.

While loops have been around for 100 years, I think that resonant small loops with tuning capacitors, are much more recent.

Many versions do have the capacitor on the top, but some don't (some AlexLoops being an example).

If the radiation being off the bottom (the side opposite the cap) is real, a possible reason why it hasn't been discovered, is if nobody set it up to measure it in 3-D space. If you keep making loops the way you've always made them, you might never know that something is going on that you didn't have a reason to predict. If you only measure the radiation in the horizontal plane, and if the measurements always look like you expected them to be, then you might never know that something else is happening.

So yes, I can imagine that nobody found this in all that time.

Or maybe nobody saw it if Mr. Edginton's measurements are flawed.

Sometimes "warming the worms" is actually useful. I am a fan of NVIS for local/regional coverage. A lot of American research into NVIS, used directional antennas that pointed straight down! The idea was to make use of the reflection off the earth (or the water table underneath), rather than trying to avoid it.

In spite of NEC's modeling problems, I still like to see some correlation between what it predicts, and what you measure. NEC is based on sound principles (e.g., Maxwell's equations), which still hold true. I would like to see studies in NEC that agree with his measurements.

Well, enough of my rant/rambling.

Andy

In the second video, he claims that antenna is <10 wavelength. The frequency is lower (10.5 meters) so I guess the loop's circumference is a meter or a little less. It is hard to gauge it from the video.

Rick,

You would do well to question the results of NEC (at least NEC 2) when modeling loops. I have found significant difference between NEC2 (MOM sim and not completely Maxwell-based) and Ansoft HFSS (FEM sim and closer to Maxwell eq's based) results when looking at radiation patterns. Actual practice (building 1/4 wavelength circumference loops) shows that the feed Z (fed with a transformer as Ben Edginton shows) is always reported to be way too low with NEC 2 based modeling. This was for both 4NEC2 and EZNEC too.

I think this is the 'dirty little secret' few people know about.

My Wellbrook ALA1530LNPro arrived today Thursday 5th and I quickly assembled it (after changing the antenna BNC plug to a more convenient PL259 plug to suit my adapters) and mounted it on a commercial PA Speaker tripod in my kitchen, then set about comparing it to my Wideband "lazy L".

The first thing I noticed was the extra gain on long and medium wave which needed the attenuator switched on to stop the intermodulation (not very happy about that) but the indoors ALA1530LNPro otherwise almost kept pace with the "L" so I can live with it.

Shortwave bands... the ALA1530LNPro didn`t have so much gain as long and medium wave so I didn`t need the att swtch on tho` it was still a bit gainy, compared to the "L" and tho` the ALA1530LNPro was indoors it picked up most stations the "L" did but with a poorer noise level altho` some strong stations were weaker on the "L".. I suppose the "L " is directional too like the ALA1530LNPro which has quite a sharp null.

Not a scientific test by any stretch of the imagination but it seems to bode well when I set the ALA1530LNPro up outside with a rotator, then compare it to the "L"

Regards.

Lee...G6ZSG

I have ordered the Wellbrook ALA1530LNPro and expect it to arrive Wednesday hopefully...??
What is the best height to mount it ??1 metre magloops are reckoned to be best at one loop width high... as this Wellbrook ALA1530LNPro is mentioned in passing, as a magloop, does this mean at 1 metre off the ground too ??
My vertical homebrew 1 metre magloop works well at 1 metre height !!

Regards.

Lee G6ZSG.

Hi Lee,

For the 1530's to perform at their best, they need to be at least 15'-20' away from the house because of all the noisemakers. I was testing a passive 35' delta loop to a 1530LN loop this morning for a comparison on TransPacific stations. Both were about 50' away from the house and actually the 1530LN seemed to do a bit better. The 1530LN also had a flatter response. It looked like my passive 16:1 transformer has some rolloff at the low end of MW. I have been quite pleased with the Wellbrook products since 2008, when I started using the ALA100 and FLG100 line.

I can't speak to the specific application you're using, but I can provide a little information about alcohol that may be relevant:

1) Rubbing alcohol usually contains lanolin or other oils to prevent skin drying that pure alcohol will cause; that's what make it specifically "rubbing" alcohol. Not all alcohol sold in drugstores is actually rubbing alcohol, though, and the oil may not be a problem for your purposes anyway.

2) 99% alcohol won't stay 99% for very long without extraordinary effort to keep it so; alcohol is hygroscopic, meaning that it will absorb water from the air (or anywhere else). The purer the alcohol, the more hygroscopic it is; that's why most common alcohol sold is at most 85%-90%; by that point the hygroscopic effect has dropped of to the point where strenuous measures to keep it under control aren't necessary any more. Fortunately, for most purposes a little bit of water does no harm.

Hi Jim, It is a sealed special order product from the former PAR Electronics, just like the 9:1 matchbox in their SWL antenna. I know it is a binocular core, but which one and what the actual winding counts are, I don't know. I don't know if the new guy at LNR Precision would make them again, but it was a pretty good deal at $24 each, not to have to do it myself. I have several 16:1's and 9:1's and they have the extra screw mounts for grounds on each side of the isolated transformer. I use them without any ground connection, but should probably experiment. I usually use Wellbrook ALA100 or FLG100 heads for my loop antennas, but I am a few miles away from 10KW and 5KW stations on a river bottom and have signals during the day at less than -10 dbm, which blows away all my SDR radios, some even with attenuation. So, I have gone passive here in GP.

As an aside, when I moved to our new home - a garden home with a walkup attic and steep roof - 7/13, I carried my Pixel RF Pro-1a from my old home, where it had been on a 5' mast attached to my low deck with it's center ~8' above ground. The mast was placed in a tripod base on the floored attic about centered in the house. A short RG6 jumper connected it to the already in place CATV (RG6) feed to my office below - I was listening in minutes. The HOA prevents outdoor antennas, so my antennas are in the attic. Well, the one loop is it for now! My previous address - for 37 years - provided room for a myriad of antennas, including LW, AD sloper, and even a TTFD. It also had an aperiodic S5-S8 EMI source that peaked on the pole in front of my house. The loop was bought to null the noise, which it did until1/12, when a tornado caused some 'urban redevelopment'.

I lost a few shingles, wind chimes, and my deck furniture - my loop spun in it's mount, winding up the coax. When the power returned, it was fine. When the neighboring streets got new poles and high voltage feeds, APC must have found more leaking insulators - the EMI came from several directions and ran S7-S9+ - the loop's nulling ability was all but useless - I quit listening. When I moved here - I finally had the bliss of underground utilities. I live in the quietest neighborhood - no EMI! Oh, some RFI from the fiber optic to twisted pair phone MODEM in a metal box in the front yard - but it was nulled by the 'loop'.

Simply stated, put the Faraday-shielded H-field loop where you can - and null interference - and enjoy it. My only problem with the Wellbrook loops was that they used BNC connectors, which were designed for indoor use. Type F connectors can be waterproof, are easily installed, and permit RG-6QS use - great low loss cable. Just put the loop 'in the clear' and you both will be 'happy'.

John

PS I posted a photo of my loop in the attic.

11214. Large Indoor AM Broadcast Receiving Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-11-10 01:08:51 UTC
From: w4msl@...
Topic: 11214 Message: 11214

I want to make as large a loop as necessary for good reception (but no larger than needed) which can be concealed behind the bookcases in my office. Orientation for the little freebie AM loop which came with my old AM/FM Stereo receiver is parallel to the wall (turning it nulls the stations of interest). So, I'm supposing that a large loop placed against the same wall but behind (non-metallic) cabinets might work better than the little loop. FWIW: I can get the stations presently, but reception is weak and a bit noisy. I'd like to get better clarity and less noise.

Here are just a couple of the rectangular dimensions I can work with:

6'x6' and 2'x7' — these are just some dimensions of convenience which maximize loop size for the given spaces but can still be placed behind the cabinets and against the wall. The FREQUENCY range of interest is 105-106mhz. I don't really need a full AM broadcast spectrum antenna, as the stations of interest fall in this narrow band. So, I'd like to know how I might determine an optimal LENGTH of wire for this frequency range for both of the respective loop dimensions, as well as suggestions for actual loop dimensions. And, could this be constructed w/o the need for variable capacitors, given that it's intended for such a narrow range? and assuming that an optimal wire length for this frequency range can be determined? I'd prefer just to run the wire from the loop directly to the AM antenna jack (mono), as I can't both conceal the antenna and place the radio within the loop proper for induction coupling.

Circles considered, but too much bother, I think, to do. Four pegs anchored behind the cabined will let me wind a square/rectangular loop, but a circle would be much more work.

Hope this makes sense. I've never tried this kind of antenna before. Suggestions appreciated and solicited.

Many thanks.

In general, those old antennas were resonated with a variable capacitor
or varactor so that they tracked the tuning of the receiver. If you
replace the stock antenna coil with some loop, the loop needs to have
the same inductance as the built in loop. This will establish the
largest loop that will work. The sensitivity of a loop is
proportional to the area, so a loop with 16 times the area
of the stock loop will give you something like 12 dB. That may
be enough. Any solution that does not resonate the loop starts
out with a big handicap and would require a huge loop to substantially
improve the sensitivity.

Here are some ratios that help with situations like this.

L is inductance, r is radius of loop, N is number of turns, E is voltage.

$Q \propto L / (r * N)$

$E \propto r^2 * N * Q$

$E \propto r^2 * N * L / (r * N)$

$E \propto r * L$

If L is constant

$E \propto r$

So a single turn loop will give the highest voltage for a given inductance.

Rick

Hi Rick,

I'm not sure your comment about loop sensitivity vs. size always applies. What you state is what I've understood for years, but recent results with the current improved models of Wellbrook 1-meter active loops are causing me to question that thinking.

A friend of mine from Grants Pass, Oregon (who was with me at the recent Rockworks, Oregon DXpedition) has been carefully comparing a 35-ft. long X 20 ft. high delta loop antenna with a 16:1 balun against a 1-meter Wellbrook ALA1530LN loop. He has been using an Elad FDM-S2 receiver to compare signal-to-noise levels of Japanese, Korean, and Chinese broadcast band signals at local dawn. He's done this for a number of days, and he's also sent me some of the "A-B" comparison WAV files to run through my own SDR software.

We are both finding that the trans-Pacific MW signals are better (higher S/N) on the small active Wellbrook antenna than the much larger passive loop. I measured the difference in most cases as 5 to 8 dB improvement. This is enough to make a difference in weak signal reception on the split frequencies (9 kHz channel spacing).

The passive loop is getting ample signal... no problem there. The amplified Wellbrook has somewhat higher noise floor than the passive antenna, *BUT* signal-to-noise on the Wellbrook is better on most cases and intelligibility of the weak signals is improved. Curiously, the only frequency for which the large passive loop was better is 1017 kHz. That signal was likely CNR1 China broadcasting in Korean, based on the UTC time and transmitter power (reception was too weak to tell if the language was Korean or Japanese).

Whatever the reason for the small loop's better performance on long-haul MW DX, my friend is happy about the findings because the Wellbrook is less noticeable to neighbors than the 35 ft. passive loop. Our results are just preliminary, but have always been in the Wellbrook's favor each day of the comparisons. BTW, both antennas are in the middle of a large field and a considerable distance from buildings, metal structures, power lines, and each other.

Make sure there is no electrical wiring in that wall.
Otherwise the coupling to the loop would be almost perfect, and you will only hear the strongest stations, the rest drowned in hum.
A very small loop (or even the internal small ferrite bar) would be better, because it can be rotated to null the hum.

My comment was in reference to passive loop gain, which
I referred to as "sensitivity". Active loop gain, and
signal to noise ratio is another discussion. The
original poster seemed to just need more signal to overcome
the noise in his consumer receiver. I'm sure the
original poster is not up for buying a $400 antenna just
to listen to local AM stations.

Hello Guy,

What you may be seeing with the ALA1530LN is that it has a near to noiseless amplification plus an optimum loop match in the AM BAND.

On the point of the “near to noiseless amplification” I had to seek professional help from Professor Michael Underhill G3LHZ formerly of Surrey University to work out the noise figure from my observations. Basically, what I was seeing when the noise floor was considerably lower than the thermal resistor noise plus the amplifier gain; was due to the amplifier having a dynamic input resistance (z in) that is noiseless except for the Jfets. Mike Underhill worked out the NF for the ALA1530LN and the ALA1530LNPro to be approx. 0.2dB, this equates to a noise temperature of 9.5 degrees Kelvin.

Subject: [loopantennas] RE: Large Indoor AM Broadcast Receiving Loop

Hi Rick,

I'm not sure your comment about loop sensitivity vs. size always applies. What you state is what I've understood for years, but recent results with the current improved models of Wellbrook 1-meter active loops are causing me to question that thinking.

A friend of mine from Grants Pass, Oregon (who was with me at the recent Rockworks, Oregon DXpedition) has been carefully comparing a 35-ft. long X 20 ft. high delta loop antenna with a 16:1 balun against a 1-meter Wellbrook ALA1530LN loop. He has been using an Elad FDM-S2 receiver to compare signal-to-noise levels of Japanese, Korean, and Chinese broadcast band signals at local dawn. He's done this for a number of days, and he's also sent me some of the "A-B" comparison WAV files to run through my own SDR software.

We are both finding that the trans-Pacific MW signals are better (higher S/N) on the small active Wellbrook antenna than the much larger passive loop. I measured the difference in most cases as 5 to 8 dB improvement. This is enough to make a difference in weak signal reception on the split frequencies (9 kHz channel spacing).

The passive loop is getting ample signal... no problem there. The amplified Wellbrook has somewhat higher noise floor than the passive antenna, *BUT* signal-to-noise on the Wellbrook is better on most cases and intelligibility of the weak signals is improved. Curiously, the only frequency for which the large passive loop was better is 1017 kHz. That signal was likely CNR1 China broadcasting in Korean, based on the UTC time and transmitter power (reception was too weak to tell if the language was Korean or Japanese).

Whatever the reason for the small loop's better performance on long-haul MW DX, my friend is happy about the findings because the Wellbrook is less noticeable to neighbors than the 35 ft. passive loop. Our results are just preliminary, but have always been in the Wellbrook's favor each day of the comparisons. BTW, both antennas are in the middle of a large field and a considerable distance from buildings, metal structures, power lines, and each other.

In general, those old antennas were resonated with a variable capacitor or varactor so that they tracked the tuning of the receiver. If you replace the stock antenna coil with some loop, the loop needs to have the same inductance as the built in loop. This will establish the largest loop that will work. The sensitivity of a loop is proportional to the area, so a loop with 16 times the area of the stock loop will give you something like 12 dB. That may be enough. Any solution that does not resonate the loop starts out with a big handicap and would require a huge loop to substantially improve the sensitivity.

Hi Andy,

Guy and I have been measuring my new 1530LN loops to my 35' passive delta. The passive matchbox is a binocular core based 16:1 transformer made by the former PAR Electronics (now LNR Precision). It does seem to have a bit of low-end rolloff, possibly from not having enough total windings to cover the low end of MW and LW. Thanks for the great new loops, which make it easy to have a small loop that matches or beats larger passive loops in performance!

Greetings W4MSL from VK land. If I have read your request rightly you want a loop to receive "frequency range of interest is 105 - 106mhz". I presume you mean Megahertz and not millihertz.. 105 - 106Mhz is in the FM broadcast band not the MW broadcast band. If this is the case a MW ioop antenna is the last thing you need!!! A full wavelength at 105.5MHz is about 2.7 metres. You say you feed the signal into a MW socket. Has your radio an FM socket? If so cut 2.7m of wire, bare the ends of insulation, touch the bare ends, appropriately, to the FM socket. If it's good you have your answer. Regards vk2tti

[loopantennas] Large Indoor AM Broadcast Receiving Loop

I want to make as large a loop as necessary for good reception (but no larger than needed) which can be concealed behind the bookcases in my office. Orientation for the
little
freebie AM loop which came with my old AM/FM Stereo receiver is parallel to the wall (turning it nulls the stations of interest). So, I'm supposing that a large loop placed against the same wall but behind (non-metallic) cabinets might work better than the little loop. FWIW: I can get the stations presently, but reception is weak and a bit noisy. I'd like to get better clarity and less noise.

Here are just a couple of the rectangular dimensions I can work with:

6'x6' and 2'x7' — these are just some dimensions of convenience which maximize loop size for the given spaces but can still be placed behind the cabinets and against the wall. The FREQUENCY range of interest is 105-106mhz. I don't really need a full AM broadcast spectrum antenna, as the stations of interest fall in this narrow band. So, I'd like to know how I might determine an optimal LENGTH of wire for this frequency range for both of the respective loop dimensions, as well as suggestions for actual loop dimensions. And, could this be constructed w/o the need for variable capacitors, given that it's intended for such a narrow range? and assuming that an

optimal wire length for this frequency range can be determined? I'd prefer just to run the wire from the loop directly to the AM antenna jack (mono), as I can't both conceal the antenna and place the radio within the loop proper for induction coupling.

Circles considered, but too much bother, I think, to do. Four pegs anchored behind the cabined will let me wind a square/rectangular loop, but a circle would be much more work.

Hope this makes sense. I've never tried this kind of antenna before. Suggestions appreciated and solicited.

Many thanks.

Sorry. I conflated one project with another! I meant AM, and supplied the FM frequencies of interest from my other project. Too many recipes for only one cook! Sheesh...glad YOU were paying attention, because I certainly wasn't when I wrote that post. Thanks. So...let's say AM frequency of 650Khz, which is close enough. So, that does make a bit of a difference...

Hello Dave,

For MW/LW you need to try to match the loop z to the receiver z. So as a compromise match the low end of the MW band to the receiver; say 50 Ohms. Therefore, a 16:1 transformer (800 to 50 Ohms) will not provide the correct match as the loop z is much lower than 800 Ohms at approx. 500kHz. Therefore, I would suggest you experiment with a 1:1 transformer.

Hi Andy,

I have the opportunity to experiment more at this location. I am next to a College and have a field that is several hundred feet across and rather quiet, perfect for comparing antennas and such. So, this gave me a real good opportunity to try a passive matchbox vs several of your loops. I could tell right away there was somewhat of a mismatch on the passive loop, but what I was really trying to see was the contrast of S/N on each, taking into account a different noisefloor from amplified vs passive matchboxes.

Frankly I marvel at how well the various Wellbrook heads do, even with a higher noisefloor compared to a passive one. Basically the Wellbrook S/N is as good or better in each case, even though the antenna loops are much smaller, ie 35' for the passive loop vs 7.5' square for the active loop. Also, I have been comparing the 1m 1530LN to these two antennas also.

One of the problems these days is that it is harder to put up a large antenna, both from a space standpoint and also from the ability to find a relatively noise-free location. This lucky location for me, really lets me see your antenna products shine under very weak signal conditions. For example, I am seeing the 400 watt HPONS stations in Australia just above the MW band consistently at 10-15db above the noisefloor on my 7.5' square loop using an FLG100 (original not new LN) head. The 1m 1530LN sees them as does the 35' passive loop. Both the 1530LN and FLG100 based antennas see as well or better than the larger passive loop, which tells me I don't need a large antenna for good results. By the way, those 400 watt stations are 7000+ miles away, just amazing to me for the MW band!

Hi Jon, signup to the Yahoo Group 'MagLoop' then go into the Files section and pull down the file: _The Underestimated Magnetic Loop HF Antenna_V1. 2.pdf. This document by Leigh Turner VK5KLT is a wealth of excellent design data. There are lots of designs that use coax, wires, aluminium foil etc and all have varying success. Leigh's document cuts through lots of folklore and tells you how to do it properly.
Good luck, 73, Derf, G8ZGK

Rather than a transmitting loop, simply get a mobile type screwdriver antenna and install it inside your flat and build the best counterpoise your circumstances permit. Ideal way to go is to cover the floor with hardware cloth mesh and put rugs over the top of it.

Alternately, make a dipole out of two screwdriver antennas back to back. This works well if your flat is on an upper floor.

It is very straightforward to calculate the bandwidth
vs size of a lossless loop (100% efficiency). To get
a usable bandwidth, meaning a percent or so, the loop
has to be between 1/8 and 1/4 wavelength in circumference.
(Above 1/4 wavelength, the "loop" acts as a shortened
and bent dipole).

If some professor did manage to make a high efficiency
loop that was below 1/8 wavelength, its bandwidth would
be so small as to be impractical.

On top band, 1/8 wavelength is 70 feet.

If you want to work top band and you live in an apartment,
put a big screwdriver antenna on a pickup truck and run
a kW mobile. KH6DX/W6 has achieved DXCC on 160 meters MOBILE.

) I can not say I have ever seen or heard of a high efficiency magnetic loop not to say such a thing cant or doesnt exist but my reason for using a loop is probably the most usual one which is antenna restrictions therefore I use a small tuned magnetic loop antenna which means it is normaly 0.1 of a wavelength in size, in fact my main loop is a 26inch aluminium bicycle wheel rim which does give me reasonable results, compare this to no results without an antenna I think its good even though the efficency is a trade off.
I was recently told about a very large magnetic loop made from a bent and welded scafolding pole on a wooden stand of some sort? which was used on 80m with a capacitor made from two large metal oil can cylinders, this loop was reported to be very good although very heavy and the capacitor had long degraded, I expressed an interest and was told it was stored in a garage somewhere and it would be collected but nothing yet? fingers crossed it comes my way.

Yes, I posted without reading the article. I said basically that you can make a high efficiency loop if you want to go to enough trouble, but it needs to be bigger than 1/8 wavelength and preferably 1/4 wavelength in circumference, but it will be quite narrowband. 1/8 wavelength is quite large on 160 meters.

I have now read the article. The article essentially said the same thing I said. The loop constructed was very large, certain not something you can set up indoors.

The rest of the article was a lot of anecdotal testimonial that nowhere gives a number for efficiency. The 0.2% bandwidth is at least consistent with high efficiency. (If you don't have narrow bandwidth in a loop, you cannot have high efficiency).

It is important to understand that none of this success with large loops will translate to smaller loops.

An additional comment I would make is that these LARGE LOOPS ARE NOT MAGNETIC LOOPS! They are shortened dipoles bent into a circle and fed at the ends. The current around the loop is not uniform due to the size. The fields are not pure H fields. Also, the polarization is not pure vertical. Doesn't mean they won't work, but they are different breed than a true magnetic loop. Thus we see that no true magnetic loop is any good as a transmit antenna. (Yes, you can get on the air with it if you have nothing else, but your signal will be weak).

Rick,
I am reckoning that perhaps you may have less practical experience orlittle actual performance data in regards to some of these loop antennas outside of perhaps the construction of a few small loops for indoor use.
VK4AMZ describes, in human understandable terms, his experience with his antenna, which is a 1/4, 1/8, 1/16 WL cir. design for the 40, 80, 160 meter bands respectively. Noteworthy in his article are the pitfalls of loop construction that some people may make, such as using poor quality materials such as lossy ceramic 'doorknob' capacitors or poor workmanship on the construction (e.g. bolted vs brazed electrical connections.)
For a more objective analysis, I invite you to review my WSPR reports or 'spots' on 160 meters made using a 1/4 wave tuned loop to stations across the US and the world from my city-lot backyard. A comparison of my signal SNR at distant stations can be made with a station off to my east, KD6RF who also operates 160 meter WSPR nightly. Signal report databases going back several years can be downloaded for inspection and review.
I would also like to try and make contact with you some evening on
160 meters on 1900 kHz for a practical demonstration. That goes for anyone else, too. I also often check into the 1910 kHz morning net in Texas, Oklahoma and Arkansas, with very good results,
For the previous two years I have checked into the 160 meter weather net on 1995 kHz without issue using only 100 Watts from the Dallas, Texas area. The bulk of the members of this bet are north of Arkansas and Oklahoma. The usual Net controls in Kansas and Nebraska have been able to 'copy' my reports. I have now migrated to the use of an amplifier (as most stations on 160 use them) and I get complimentary reports on my signal.
I and probably a lot of others are also interested in the 'first principles'in physics that would be the determining factor in establishing the cutoff point for efficiency in antennas aside from what we already know about conductor skin resistance and capacitor dielectric loss whichaffect loop antenna efficiency directly. Mike Underhill has looked at thisissue extensively BTW and does not make quite the same claims as you make.
Regards,
Jim WB5WPA

Jonathan,

search the QST archives for June 1986, a construction article by Ted Hart, W5QJR about building magnetic loops. I built one back then and I have been a believer ever since. The capacitor and a method of remotely tuning it will be the difficult part. But these antennas work and work very well. I had the one I built in the attic for several years. But the remote tuning is a very important part. These will tune very "fast", meaning the angular increment in capacitor rotation will be a much larger then you'd imagine difference in frequency. But the antennas are very narrow band and very careful tuning is mandatory.

You'll also see many comments from those who get very distracted by theory and numbers. Pay them no attention. Build one. Enjoy it. I wouldn't worry at all about RF fields. 50 watts is nothing to speak of. In Magloop yahoo group you'll find Leigh VK5LT and his "white paper" on the subject. Believe what he writes, his information is very, very good. And very practical. AND he knows the theory very well. You'd be best served by joining the MagLoop group. "Loopantennas" seem to be more about receiving loops.

But these antennas do work exceptionally well. Can I tell you how many db difference to a dipole at 1/4 wave? No. And that doesn't matter one bit. The mag loop works. My first QSO from the 3' diameter loop on my book shelf manually tuned was a station in Japan on 40M CW with 100 watts. I am in Texas. He gave me the report 579. At that point who cares how many db difference or what the exact efficiency is?

BTW, 80-30 in one antenna may be impractical, as far as tuning range and capacitor are concerned.

Take care and good luck with the antenna.

Just so we know what we are talking about, does your
loop lie in a vertical plane or a horizontal plane.
If the latter, how high is it?

Glad you are having fun with your loop. This morning in the DX
contest, many signals from Asia were 40 dB over S9 on a calibrated
S meter. Compared to that, S7 is nothing remarkable. Your
loop with 1/14 wavelength circumference is at the upper end
of true magnetic loops (1/10 wl max). You are probably
several S-units down from a non-compromise ground plane. Maybe
you don't care about that disadvantage, but many ops do.
In a contest, you would really notice it.

I can easily work JA on 40m phone from my mobile station.
What does that prove?

For anyone interested. Section 6 on my QRz.com page contains a table of objective measurement results between 3 different magnetic loops and my reference dipole. The bottom line is that a well constructed loop using large diameter copper pipe performs at about one S-unit down from the dipole at half wavelength height. Quite respectable performance for a 5 ft diameter loop at 10 ft above ground.

Nice work on the 40 meter loop, but with a perimeter
of about 1/8 wavelength, I would quarrel with the
description "magloop". With the bandwidth well under
1%, you very well could have fairly good efficiency.
You might have been able to get similar results if
you just put a 13 foot high screwdriver antenna on
your car, at a lot less cost and effort.

Thus we see that no true magnetic loop is any good as a
transmit antenna. (Yes, you can get on the air with it if
you have nothing else, but your signal will be weak). <snip>

Oh no ! Now I have to void out all the DX contacts I made with great signal reports on 20 meters made with my 2.5' diameter loop - DARN IT ! ;-)

No, you just need to stop referring to it as a true magnetic loop. At nearly 1/8 wavelength, it is too large to qualify. That's my point. As the size of the loop is increased, it starts to work (albeit with narrow bandwidth) at about the size where it has outgrown the true magnetic loop category.

Why does it matter whether a loop is magnetic as long as it gets out to whatever extent? The reason is that when a loop gets sufficiently large, it can be replaced by a Moxon bent dipole using the same amount of wire, so as to fit in basically the same space. Since this uses wire, not copper pipe, it is much cheaper and easier to build. You do need a loading coil for this bent dipole, but I submit that is a lot easier to build than a big loop made out of pipe. You also don't need a vacuum variable to tune.

The reason is that when a loop gets sufficiently large, it can be replaced by a Moxon bent dipole using the same amount of wire, so as to fit in basically the same space. Since this uses wire, not copper pipe, it is much cheaper and easier to build. You do need a loading coil for this bent dipole, but I submit that is a lot easier to build than a big loop made out of pipe. You also don't need a vacuum variable to tune.

Well, my loop has about 7' of 1/2 inch soft copper tubing in it which is smaller than 1/8 wave, it doesn't have a vacuum variable on it either. It uses a dual gang air variable cap on it that I tune by hand. It was very easy to build, I just bent the pipe around a metal drum to get the shape and then soldered the connections to the variable cap and then made a feedloop out solid #12 copper wire. Took me all of a half hour to build it. Regardless of what you call it, it still amazes me everything I make DX contacts with it using a little pipsqueak SW-20 qrp rig at 2 watts ! If its not a magloop, please tell me what it is.

Still bigger than 1/10 wave, so it exceeds the generally recognized size
of a mag loop (some references use 1/12 wave).

> It uses a dual gang air variable cap on it that I tune by hand. It was

That will work if you only want to run 2 watts.

>> rig at 2 watts ! If its not a magloop, please tell me what it is.

It is a "large" loop. Not a magnetic loop.

Still bigger than 1/10 wave, so it exceeds the generally recognized size
of a mag loop (some references use 1/12 wave). <snip>

So now its changed ? It was 1/8 wave, now its 1/10 or 1/12 ? Hmmmm ?

> It uses a dual gang air variable cap on it that I tune by hand. It was

That will work if you only want to run 2 watts. <snip>

It will work with 100 watts if the plate spacing on the cap is wide enough

>> rig at 2 watts ! If its not a magloop, please tell me what it is.

It is a "large" loop. Not a magnetic loop. <snip>

Large compared to what ? A full wave loop on 20 would be about 16' square and a halfwave dipole is about 32' long and you call a 2.5' diameter loop "large" - interesting ! None the less, it works and works quite well and it fits in the back of my car and sets up in about a minute with no assembly required.

GOOD NUFF FOR ME !

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-12-01 14:25:10 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11252

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Hi Rick,Can you please cite your sources? My understanding from doing a lot of reading is that an antenna can be considered a magnetic loop antenna with a loop anywhere from about 1/10 to 1/4 lambda. The loop operates as a parallel tuned LC circuit. The tuning range is determined both by the variable capacitor size and the loop size. The practical range is limited on the high side by the self-resonant point of the loop (calculated from the inductance and self-capacitance) and the low side by the bandwidth. I would not want to design a loop that had a bw of less than 3 KHz, otherwise not very useful for SSB. After about 1/4 lambda the loop acts more like a balanced dipole, but this description is referring more to the radiation pattern. A STL has null points that a dipole does not. Further, I was under the impression that a Moxon is actually a 2-element beam antenna. Balanced I will accept, but isn't saying a Moxon is a dipole like calling a Yagi a dipole? Also, a Moxon is not multiband, where a STL can give very good performance over several bands.
This looks like the start of a very good discussion and I look forward to your response

That will work if you only want to run 2 watts. <snip>

It will work at 100 watts if the spacing between the plates on the cap are wide enough so as not to arch over when transmitting !

>> rig at 2 watts ! If its not a magloop, please tell me what it is. <snip>

Loop, large loop, magnetic loop, small transmitting loop, whatever its called, who really cares as long is works and works well. In fact, my little junkbox copper pipe thrown together in a hurry thingamajig loop works just as good as a halfwave dipole and it will do that while sitting about 3 feet off the ground and I don't need trees to hang it from !

11256. Halo

Yahoo group: loopantennas (2013 — 2017)

From: Will
Topic: 11256 Message: 11256

Hi All,

This discussion as to what sort of loop is a loop reminded me that way back around 1970 in UK I used a Halo as 2m mobile a/e. It worked well as mobile a/e for back in those days, clamped to car gutter so no holes in work owned vehicle. The halo was about a foot off the vehicle roof. I don't recall that there was specific spacing Converted Pye Reporters and other similar things. Often from Garex.

Now it is loop, well it was circular. Tuned by capacitance between ends. Fed with gamma match. From memory it was some thing like 12 or 15 inches across. That makes circumference about 1/2 wave, in other words a dipole bent into a circle.

Now is that a loop or not?

Cheers,
Will,
ZL1TAO

Exactly! Too many people hung up on specs and theory and not enough building and enjoying. The antenna doesn't know that it's not a magnetic loop by some definition. Go to Home Depot, buy some copper, build an antenna. Pretty much what I did (ok, add big-arsed capacitor and Hurst stepper to control it) And enjoy it.

Need to lighten up...it's a hobby...

11258. skywire loop install issues

Yahoo group: loopantennas (2013 — 2017)
Date: 2015-12-12 03:51:49 UTC
From: verstelle@...
Topic: 11258 Message: 11258

Hello everyone, well I have been using a 43' vertical at the home QTH and decided to put up a horizontal loop over the house. I have read many great things like how quite they are. So I put up a 40 meter full wave loop about 145'.

So I installed the loop and put a 4:1 balun on it and sweeped it for SWR and it was a little off but close. I have never used Ladder line so decided to try it and that is when things went bad. There was no dip at 40 meters at all and the rig tuner cant tune it. my I has a dip at 15mhz, 20mhz and 32mhz.
I had read that ladder line can have a issue at some lengths so I spliced on 10 more feet but still weird results. I removed the ladder line and put the 4:1 balun back on and used coax again, and now my antenna is back to normal with good swr on 40,20,15 and 10meters.

Now I was hoping it would be better than my 43' vertical but the loop is noisier than the vertical and some signals are a little better on the loop and some are better on the vertical. in most cases the vertical is a better antenna.

I really thought a horizontal antenna would be quieter so i'm a bit disappointed. Anyone else have this kind of experience?

I'm wanting to get a better antenna up but because of cc&r's I don't want to push it with a tower and a yagi. I have never had great results with a ground mounted vertical and during the California QSO party I struggled to get over 100 contacts when others in the local area were getting contacts left and right.

right now i'm up about 25' and I could go up another 5' but doubt that would make a big difference. Also I'm feeding it about 2 feet from a corner, it is in a square configuration. Would changing the feed point make any differences?

Just trying to come up with some ideas before I take it down and try something else.
thanks,
Bill N7OQ

Even if we disregard the weird pattern of a loop 4 wavelengths long on 10 meters, etc., and the feedline decoupling issue, your height of 25 feet is just too low for horizontal polarization on the bands below 15 meters (and it isn't great even on 10 and 15 meters). If you have to be close to the ground, you must use vertical polarization.

I am assuming your 43 foot vertical is just a plain vertical (without traps, etc). There is no magic in the number 43 that is going to make the same height work right on 40,20,15, and 10 meters. I recommend you replace it with a BigIR vertical elevated 10 or 15 feet and install two elevated 1/4 wavelength radials per band. Your total height will be about the same 43 feet, it will just work a lot better. You could also use a trapped vertical, etc.

Actually, a moderately low horizontal loop is not necessarily a bad performer. It'll tend to be a cloud burner -- a.k.a. NVIS -- on the lower frequencies so don't expect the greatest DX from it. If you could raise it about 50% more it would be considered high, and better for DX on 40m. It's probably a little too high already for 20m.

One potential problem, though, is that it is so close to your house. You mounted it over your house, right? So it's picking up the noise from all the electrical circuits in the house. (That, and the house wiring probably acts as a messy reflector too.)

There's also the chance that it has a bad connection, causing both the poor performance and lousy SWR.

It is not always true that a loop is quieter. I don't know why ... except for faults, or things that unbalance the loop. But it happens.

The nice thing about ladderline is that it tolerates large SWR with less loss than the equivalent situation with coax. But if the SWR on the feedline is big, then it (either ladderline or coax) has the potential to transform the impedance into something so far removed from what the antenna matcher "wants" to see, that it can't handle it. If the loop's feedpoint is around 100 ohms and you use a wide ladderline that is about 600 ohms and it happens to be a quarter wavelength long, it would transform the impedance up to 3600 ohms. That's an SWR of 72:1 in a 50 ohm system, or 18:1 if your antenna matcher uses a 4:1 balun at its output. A theoretically better situation might be to use a half wavelength long ladderline.

If the SWR you measure with coax (without the benefit of the antenna matcher) is low already, then I think you shouldn't worry about the coax's loss.

If your 43' vertical hasn't got at least a few counterpoise wires or radials, then adding them would probably make that antenna get out better.

Andy

Hi guys well it took so long for this message to post I went to qrz and have fixed my problems. First I was to close to a metal chimney less than a foot from it and it is metal all the way to my fireplace. So I replaced the poles and now I'm up to about 35' and now it works really good. It works better than the vertical in most cases but not all the time. I understand a horizontal loop has a feed point of about 100 ohms so the 600 ohm ladder line might not be the best choose maybe 450 or 300 would be better. But my feed point is right above my shack and I'm using 50' of rg8 and a 4:1 balun. I'm going to wind a 1:1 balun and try that instead of the 4:1. My swr' are 2:1 on 40, 1.3:1 on 20 and 1.4:1 on 15 and 10.

My 43' vertical has over 20 buried radials and it is still quieter than the loop. I plan on adding more radials if I decide to keep this antenna. We had a storm with 50 mph winds and the loop had no problem at all so I may put it up another 5'.

What really surprises me is my magnetic loop I built to use with the RV, it sometimes beats the vertical and most of the time it is as good and it is only a few feet above the ground. I plan on building another one for 20 and 40 meters the 2 bands I use the most and I will only put up the 3' loop when the upper bands are open.

Dear Bill,

Thank you for your feedback on what worked and what did not work for you! Question: how have you secured the poles to stay upright (which base do you use?) and what kind of poles do you use? Any weblinks to the items would be appreciated as I've contemplated similar setup as you describe but just can't work out how to keep the poles from falling over :)) I should say that I have many trees here which off and on drop some large twigs which I fear will tangle with wire and bring everything down... Thank you in advance!

Math correct, but an antenna with a condenser it's a resonant antenna and with an highest Q, so you must consider Q factor effect as usual.

Poles really are not necessary. Go to WalMart and buy a $7 sling shot, some 3/4oz lead weights, a zebco fishing spinner reel, and a spool of 15lb test fish line and shoot into the trees. I did that and my 80mtr loop is up about 80 feet. Yes you are going to miss a couple of times, and you may have to sacrifice some line and maybe a weight or two to the tree gods, but it is fun and a good experience. You also do not have to have the loop absolutely square. Mine is 277Feet long and has 4 unequal sides and I get about a 1.5vswr on all the regular bands, 80, 40, 20, 15,and 10 not the Warc bands and I feed mine in one of the corners with a 100ft roll of RadioShack 300ohm line to a 4:1 balun at the window of the shack and about 10 feet of coax to the radio. No tuner needed. I used the plastic insulators from Home depot and purchased a 1000ft roll of parachute cord for hanging the insulators from the trees.

Well the problem with Quad copters is that they dont fly through the trees very well. I like to hang the ropes in a tree branch crotch. they are not way up in the skimpy tree branches. Anyway it was a suggestion and this is a lot cheaper than the poles.

Dear OMs,

Thank you for your replies directly to me as well as via the group! My problem is that trees are either too close to hang wire up far enough away, or too far away (at two corners of the quadrangle) to make it happen. I will thus have to use poles by necessity :(

Again, thank you for your replies and Merry Christmas!

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11269. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-01-01 14:02:15 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11269

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Steve Greenfield

11270. Recommendation for Loop Tuner

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-01-16 07:14:57 UTC
From: TomSwango@...
Topic: 11270 Message: 11270

I would like recommendation for a automatic loop tuner for hf bands 100 watts would be nice but not required.

Also is a loop tuner different from a regular random wire tuner or do tuners tuner what ever is connected to them

thank you
Tom

11271. Longwave Portable loop design?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-01-21 22:40:24 UTC
From: g790x@...
Topic: 11271 Message: 11271

Hi,
A total beginners question! Apologies in advance!
I'd like to build a portable tuneable LW loop for approx 150kHz to 280kHz - something similar to the Tecsun AN-200 which I have but is MW only - for inductive coupling to the radio's ferrite rod.

Is this possible with a loop diameter of 30-45cm (18inches) or pointless with such a small loop diameter?
If so, approx how many windings? I had a look at this online calculator which suggest approx 30 turns...
http://www.angelfire.com/mb/amandx/loop.html

Should the windings be side-by-side / spaced?

Can the Tecsun AN-200 be (easily!) modified for longwave?

Parts I have for a build:
- a (1970's) two gang air variable cap (approx 100pF-800pF total)
- enameled wire (0.6mm / SWG 23 / AWG 22)

Many thanks!

Topic: 11270 Message: 11273

Tom,

I built a 2 element horizontal directly phased loop beam interfaced with a remote SGC 239 Smartuner several months ago. The antenna is cut for 15 meters and is at approximately 25 feet above ground. The tuner easily matches the antenna on all ham bands 10 through 80 meters. Obviously, the effective transmitted field strength suffers at the lower frequencies since the antenna is physically smaller than the design frequency, however, based on Reverse Beacon Network CW tests over an extended period of time over several weeks, my received signal above the baseband floor at the receiving location, was as much as about 6 dB on 40 meters at about 1,000 miles, 15 dB at 10 MHz, and 10 to 15 dB at 20 meters. These were daytime or late afternoon report returns. From the Los Angeles area, these were receiver returns as far away as New Jersey, Puerto Rico, Hawaii and Venezuela as well as the mid section of the US. Applied power was about 90 watts.VSWR did not exceed 2:1 which is the design criteria maximum for the SGC tuner algorithm.

The SGC tuner takes 2 to 5 seconds to automatically adjust to a never used frequency and tune time is virtually unnoticeable when it has the frequency already in it's memory. 200 watts is the advertised power limit on this tuner.

I recommend this tuner.

As for your second question, you will find that there is a lot of controversial discussion regarding the term "tuner", "coupler" etc. From an EE standpoint, all of these terms/methodologies basically mean that the load impedance (antenna) is matched to the source impedance (transmitter) for maximum power transfer. There are practical limitations based on the specific design of the "impedance matching device" that you are using to interface to the antenna, whether it is a loop or a simple wire....but I think you get the gist of what I'm saying. You will not know if you get an impedance match until you hook it up and try it with your individual systems architecture.

Hope this helps.

Alex

If there is an interest in a horizontal loop, I have an article posted in the files section on a 80 meter loop that works on all band 80 through 6 meters, with the exception on 60 meters and it is resonate in all of those bands. I am feeding it with coax, using a 4:1 current balun. My K3S built in antenna tuner allows coverage in all of the bands, including the WARC band, with the exception of 60 meters.

Hi Rik,
You may be asking about a Horizontal loop for receiving, based on the article I have posted in the files section. All I can say is my 275' is an excellent receiving antenna and might work well for you. Mine is strung through the trees in my back yard, so that could work for you. The additional length that you could run your should be even better. Al I can say is give it a try. You will need a 4:1 balun to match it to 50 ohms.

11277. Really strange-excellent ALA-1530 Loop Results recently!

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-01-30 01:19:32 UTC
From: kb8nty@...
Topic: 11277 Message: 11277

Cant tell you for how long band conditions here in Ohio have been about the worse I have experienced.

I use a Mosley TA-33M-WARC, and Butternut HF9V vertical with about 125 ground radials or so.
By chance I switched over to my ALA-1530 Wellbrook loop and couldn't believe that bands which had nothing but atmospheric static now with using my loop signals just appeared right out of the noise!
This experience occurred on just about every band and or frequency...

My Wellbrook ALA-1530 allowed me to work the most recent DXpeditions, including a new one VP8STI which on 40 meters a switch to my ALA-1530 5' high loop brought this station completely out of the s-5 s-8 atmospheric static!

For some reason I hadn't been selecting my loop on my antenna switching recently and boy-wow am I glad I did!....

This occurrence seems to be so defining I mean honestly, from absolutely zero copy and pure static, with no sign of anything, and switching to the loop...she made stations appear right out of this horrible band noise!

Just wanted to share, possibly if you have Wellbrook loop or similar you just may share this same results!

So strange, and am sure it has to do with this unique bad propagation, by however the signals are coming in or something, as my loop never performed these unbelievable results, with normal conditions back before these recent super-poor conditions.

I mean I always have enjoyed the results of my ALA-1530, however using it together with these poor conditions have resulted in some true-pure-never experienced magic!

Just sharing...Give yours a try!...I sure hope the same for you!

From what I read Online even a 200-300 foot long wire on or near the ground acts like a BOG. By that I mean it picks up off the ends rather than the sides like a true aerial [elevated long wire antenna].

I have no idea what happens to the impedance as a single turn horizontal loop is moved from well above the earth to being close to it. Other things probably change as well. Since it is so much easier to lay a wire on the ground than attach it to trees or other supports, I am thinking about trying that. I will not be able to bury co-ax feed line until after the ground thaws. At the moment I am thinking a 1,000 foot perimeter equilateral triangle horizontil on the ground. A LOG antenna I guess [loop on ground]. That would fit on my lightly wooded land to one side of my house. Each side would be 333 feet, and the ends of each run would widen the pattern off each corner. I think it will be pretty omni directional, with minor nulls perpendicular to the middle of each leg. It is possible signals flowing around a triangular loop will cancel or be out of phase? I have no idea.

I figure if the wire does not work like that, I can roll it back up for some other more likely antenna design. I have spent hours looking for some one Online who has done this before. No luck so far, but I have to guess what anyone might call such an antenna. From what I have found, an aerial made as a horizontal loop is most omni directional as a triangle. That makes sense off the sides of each leg. For a BOG like pattern, the ends 60 degrees apart would spread the patterns off the corners to be pretty good 90 degrees wide covering 270 degrees toal with 3 nulls in between each 30 degrees wide but over lapping weakly based on Geometry, if there is no phase or cancellation effect, but that is just a guess.

-FARMERIK

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11282. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-02-01 11:55:21 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11282

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Steve Greenfield

11283. Simple Varactor-Tuned Loop by N7ZWY

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-02-19 12:46:11 UTC
From: f8dql@...
Topic: 11283 Message: 11283

Hello,
I am planning to build the Simple Varactor-Tuned Loop described by N7ZWY.
The documentation is quite clear, except for the T2 and T3 transformers.
I can read "Transformers T2 and T3 are both constructed with four turns of #30 AWG trifilar wire through the holes of a Fair-Rite 2843002402 binocular core. Fig. 6 and Fig. " but both Fig 6 and 7 show a bifilar winding, not a trifilar.
Could someone help me to undesrtand how T2 and T3 are made?

Plus, would this antenne be more efficient with multi-turns 1 meter (3 feet) loop?

Thanks for your help, 73

>

If you look closely at the figures by enlarging them in your PDF viewer you can see that I used shading to illustrate how the three wires are interconnected. I might have been better if I had used a coarser setting when I filled those.

>
> Plus, would this antenne be more efficient with multi-turns 1 meter
> (3 feet) loop?
>

No. The induced losses increase with multiple turns. To improve the efficiency you need to use larger tubing, such as 1-inch copper pipe. To ben it you need one of those expensive Harbor Freight tubing benders.

You're saying that you cannot see the obvious three forms of shading that depict the three wires of the trifilar winding? That's as clear as you can possible get.

Mr. Trask,

Would the varactor tuned loop be suitable for low power QRPp transmissions? I understand that significant voltages would develop across the varactor even at low power, but wouldn't you be able to fix that by using a higher-voltage varactor (to a certain power level)?

Dave

Dave,

I hope you and Chris don't mind me answering here. The capacitance of a varactor diode is determined by the reverse bias voltage across it. If you were transmitting with even a few milliwats of power and kept the RF voltage across the diodes below 20 volts, the RF sine wave would cause the capacitance, and thus the resonant frequency of the loop, to sweep at a rate equal to your transmit frequency. This would ruin the tuning effect, and the non linearity would probably also generate lots of harmonics.

Greg Ella

Greg,

Thanks for the reply. I kinda suspected that was the case - I was wondering if it was possible to specify a diode that would make the RF sine wave voltage small compared to the DC biasing voltage. I realize that one would need to have a high voltage bias supply in that case.

Dave

Palomar Engineers Loop Antennas LW-MW-SW2
Palomar's Loop Antenna gives superb performance on the AM medium-wave broadcast band. The loop rotates and tilts to give deep nulls so you can eliminate local interference. It also allows you to null out a station and listen to another one on the same frequency.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11296. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-01 12:17:50 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11296

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Steve Greenfield

11297. Crystal radio spiderweb loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-01 20:13:03 UTC
From: Steve Greenfield
Topic: 11297 Message: 11297

I will be doing a crystal radio workshop, I'm toying with which design to use. This fits on a letter size sheet of paper.
https://groups.yahoo.com/neo/groups/loopantennas/photos/albums/952458711

If that link quits working, go to Photos and AE7HD.
Spiderweb coil, 100t of 24g enameled wire, measured at 1600uH. I plan on adding taps. I have some variable caps from Amazon, rated 20 to 126pF. What I measured on the cap is 11 to 195pF, and 15 to 87pF. Clearly I need a lot less than 1600uH to tune the AM radio band. So I expect to redo this spiderweb coil with a larger center. The idea here is to make a large tuned loop so that a longwire antenna is not required, at least for stronger stations.
I'm using the AADE LC meter.

Hello;

From what you state on your post, you have a dual (?) capacitor that when connected would be 26 to 282 pf. To tune the AM band, a coil of around 360Uh would tune 499-1645kHz according to the calculator. It was difficult to see what diameter former you were using, but 1600Uh is way too much.

I also found out that when I imported the DXF into CorelDraw, it blew it up to fit the page. So I ended up with a coil about 2x larger than intended.

I did some calculations on it, I'll just remake it with a larger center but still large. Then the center should be large enough to fit a home-made capacitor made from a couple of CDs.

Steve Greenfield AE7HD

Hi all

I used to work with STAREC when I worked for THOMSON (a french defence systems compagny) a long time ago. STAREC was one of our subcontractors and supplied us with high quality and ruggerized HF, VHF, UHF and microwave antennas for Armes, Navies and Air Forces systems.
STAREC disappeared in 1998 when they joined RAYAN and CHELTON (COBHAM ANTENNAS nowadays).

I should still have some STAREC HF loops data sheets somewhere in my cellar (or in my shack ??). If you get the exact ref of the ebay STAREC loop, I'll be pleased to forward you the detailed spec.

It's now up to $3800.

I would say, "wow, this thing is hot!", except there are only two buyers, they are using automatic bids, and a few of them were out-bidding their own previous bids ... which doesn't make sense unless there is some sort of game going on.

You have to understand how the automatic bidding works. It only records successful bids. If I bit $2500 but the current bid is $1000, it will show the lowest number needed to outbid $1000, say $1100. Then if someone else bids $1200, it will record *my* bid of $1300 and not the $1200 bid because it was not successful. If I keep upping the bid by $100, the recorded bids will continue to be the other guys bids, outpacing mine by the minimum each time until I finally bid enough to get above his highest bid. Only then will eBay record my bid.

In general, it is not a good idea to bid until the very end of the auction. Know what you are prepared to bid and wait until the last 30 seconds to bid. Then the other guy won't have time to think about how much to counter with and you may catch him flatfooted. By bidding early you just drive up the price giving the other bidders time to think and react.

Rick

Sorry, I'm not an ebay user ... and I don't understand what you wrote.

But what I think I am seeing (looking at all bids, including automatic), is a bidding war between two bidders, who are mostly just leap-frogging one another. I guess what's happening is that one guy's non-automatic bids are competing with the other guy's automatic bids.

In any event, it is now less than 24 hours left, and the highest offer is now up to $4250.

I still say "wow".

Yes, that was my thought too.

Especially that first one, for $2500, waaay above the asking price.

Topic: 11302 Message: 11312

The bidding doesn't work that way. Starting price is $1000 and a***a bid $3200. The displayed bid would have only been $1000 until someone else bid against it. Then a***a's bid will show as the minimum over the other person's bid or in this case $2500. So 2***9 must have bid $2450 (the minimum bid seems to be $50). Then 2***9 bid $2700 raising a***a's bid to $2750, etc. 2***9 kept raising his bid a little at a time until he finally got above a***a's original bid of $3200 by bidding $3333.

Is that more clear? I expect the early $2500 bid was because 2***9 thought he was putting in a bid large enough to beat a***a and have some margin on top but a***a's original bid was still larger yet.

Read about incremental and automatic bidding...

Hi Jean-Luis,

it would be interesting to see how the feedpoint was arranged, and the measures/size too.

From the picture it looks like the feed point would be double.

Can you please load the technical information on files?

Merci et a bientot

11315. Getting the Loop UP, sugguestions?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-15 11:32:50 UTC
From: fsurovec@...
Topic: 11315 Message: 11315

As soon as the weather clears (and it is starting to look pretty good out there!) I will be attempting to put up my 80 meter Skywire Loop antenna. As far as wire antennas go the only thing I have worked with was a 40 meter dipole..... not too much to worry about there! With about 270 feet of wire I was wondering if there was a technique to follow with respect to measuring, pulling wire thru insulators and secure way to attach the ladder line to the wire itself to help keep the strain off the feedline? They make that neat plastic "T" contraption for a G5RV and 450 ohm ladder line, but it would not work in this application because I made my own feedline AND the strain of all this wire would be too much for the plastic connector anyway. I am planning to have the antenna wire "float" thru insulators at four locations so that should be interesting. I just don't want to wind up with a bunch of kinked (14 gauge) wire around my feet and all over the yard! Any light that might be shed on this would be greatly appreciated. I will keep you posted as to my progress!

Francis, WA3GGV

Hi Gian

First of all, I have to find that damned STAREC data book again. It is carefully stored ...somewhere, but where ?

STAREC used many different designs, so the part number would be interesting to know.

Some simple loops use a HV motor driven capacitor, but others are capable of fast frequency changes (some tens of ms for large frequency jumps in ALE mode)

11321. How does a shielded loop work?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-19 06:53:10 UTC
From: numeric@...
Topic: 11321 Message: 11321

I do not get it. Is there a difference between a dipole placed in a Faraday shielded room and a shielded loop antenna? A Faraday shielded room will cut emissions by a huge factor, maybe 60 db or more, yet a shielded loop antenna seems to do fine. Either the shielded loop antenna is not really shielded or my concept of shielding is wrong.

Shield is a long and well understood concept that applies to electro-magnetic shielding, not a circuit board designed for Arduino or Raspberry pi boards.
Even the ARRL may be getting badly confused, this month they review a "shield" with receive and transmit capability. "HobbyPCB RS-UV3 Radio Shield". Page 49 April 2016. Must be their notorious April fools joke.

Thanks

Yes, there is a difference. A Faraday cage completely shields what is on the inside. A shielded loop antenna does not have a complete shield. In fact, the shield is actually an essential element with current flowing on its surface. There are many references.

Nope, Rick, you have a popular misconception of a "Faraday cage" with that description.

NOTE WELL the 'break' in the shield of a "shielded" loop at the top or sometimes the bottom, allowing such loops to be responsive to an incident "H" field but NOT (so much) to the E field.

Consult a good physics or EE textbook to confirm what I am saying.

11326. Re: [loopantennas] How does a shielded loop work?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-19 09:49:38 UTC
From: H_rax
Topic: 11321 Message: 11326

I'll try to explain, but please excuse my poor English:

An unshielded loop antenna is sensitive both to the magnetic and to the electric component of the hf-field. The electric component produces the so called "antenna effect" which highly is undesirable because it contains most of local electrical disorders. A shielded loop therefore in fact is Faraday-shielded to keep off the electric component, but this Faraday shield must NOT form a closed circle, because this would produce a shortcut for the magnetic component. A nice loop antenna can be made from a coax cable using the inner conductor for the magnetic loop and the outer shield as a Faraday shield grounded on only one side and open on the other side. The loop can be used either as a tuned or as an aperiodic circle. For both modes the loop carefully should be adapted to the input of the rx or the output of the tx.

About April fool jokes: I remember a joke in the ARRL-qst in the early sixties last century: a transmitting tuned loop up on the ridge of the roof. Shortly thereafter various articles had been published discussing the magnetic loop as a transmitting antenna, the "Army-Loop" in Vietnam as an example.

Topic: 11321 Message: 11327

The shielded loop is in a conductive tube with a small insulated gap. The passing wave induces a current in the wire inside the shield magnetically however the electric field is shorted to the tube and so screens the inner wire. Formally very widely used in direction finders where it is desirable to have the nulls 180 degrees apart where there are a lot of nearby conductors e.g. a ship or plane. The shield is normally Aluminium, it greatly increases the capacitance to ground and so reduces the tuning range if you want to resonate the loop.

If the loop is not screened then the “figure of eight” (a cosine curve for small loops) is degraded if one side of the loop has more capacitance to ground than the other (about the vertical axis

To some degree you can force balance in an unscreened loop by using a coupling transformer which has a grounded centre tap on the loop side, that is a very common approach some active commercial loops take.

Some loops include a resistor to cause the loop to pick up the electric field as well as the magnetic changing the polar diagram into a heart shape, a technique used in the 1930’s.

Electrical Communication was an ITT / STC house journal. You can find the issue with Marchand paper at:
http://archivodigital.coit.es/uploads/documentos/ec/1939-1947/vol22-1944-02.pdf

Subject: Re: [loopantennas] How does a shielded loop work?

I just uploaded the Libby paper into the group files section. I cannot yet find my copy of the Marchand paper, so I may have to get another copy the next time I visit the ASU engineering library. I think that "Electrical Communication" was an IRE publication.

Thank you Helmut for your reply.

Your comment answers my question. "A shielded loop therefore in fact is Faraday-shielded to keep off the electric component, but this Faraday shield must NOT form a closed circle, because this would produce a shortcut for the magnetic component."

I have never seen a shelled loop antenna up close to see the departure from a closed loop. Now the concept makes sense. It would be very helpful if the loop antenna could be analyzed using NEC2. Its fairly easy to write a function to create a wire grid of any shape; but, will NEC2 or even NEC4 provide reasonable results? More fun with Pascal Object Orented programming (POOP) programming!

Thank you again.

They might, though I don't know of any examples where they were used for transmitting. A distinct advantage to these two forms of loops is that they act as impedance transformers, making the terminal impedance four of more times higher than that of a non-shielded loop, and when used as an active antenna the higher signal voltage resulting from that transformation helps to diminish the input noise voltage of the amplifier.

Chris,

I have read the papers on Moebius Loops by Carl Baum that explain the four fold increase in signal voltage. What happens to the inductive reactance in a Moebius loop? Could we not obtain the same result by using a step up transformer instead?

Also what happens to the inductive reactance of a loop in short circuit mode? My understanding of the inductive reactance in this case is poor to put it mildly. I am trying to learn here.

I have the following simple logic which might be too simplistic to be correct: If we connect a separate inductance to the terminal ends of a loop then the resultant inductive reactance goes down provided the two inductances do not couple. So we can continue to decrease the inductance of the second inductor to a point where the total reactance goes to zero or in other words we have a short.
Does this happen when we use an amplifier with a very low input resistance like the ones you published.
This view might be right or wrong but it was somewhere confirmed when reading about current transformers. One article mentioned specifically that a short in the secondary winding would result in a zero impedance of the primary winding.
If using the loop in short circuit mode reduces or removes the inductive reactance then why is it that the active loops with current amplifiers seem to be less performing at the higher frequencies like the ten meter band or CB band? Is this not the result of the inductive reactance which is not completely suppressed?

I'm a member of the helically_loaded magloop antenna Yahoo group. Our leader, Rich K8NDS, has what are effectively "Moebius loop" antennas on his QRZ page. If you follow the helical windings on his dual-loop antennas, you will find that the windings make each lobe out-of-phase with the other. (Using the Right-hand rule - with your thumb in the direction of an instantaneous current through the loop structure). Thus, magnetic flux is into one lobe and out of the second. Does this enhance the magnetic field to be a circulating "donut" shape? Or does this have a negative impact on the antenna performance? Empirical evidence seems to indicate that those figure-8 antennas do work, but how efficient are they?

You can, but the low impedance at the loop terminals makes the design of the stepup transformer quite an ordeal as the induced losses from the transformer core come into play. Take a look at my paper on an alternative design of a transmitting loop:

http://www.home.earthlink.net/~christrask/Paper012.html

No, it remains as it is an integral part of the loop itself by way of it's self-inductance, though that concept is not entirely accurate unless you apply the transmission line concept taught by Linville.

There's much more that comes to play when you operate a loop antenna at higher frequencies, especially when you approach the perceived parallel resonances which are more accurately viewed as a transmission line with a short for a load. See if you can find a copy of my two-part QEX article on active loop antennas where I discuss the transmission line viewpoit, as well as the benefits of using larger diameter conductors to improve the Q.

Chris,
Thanks for taking the time to reply to my burning questions.
I am familiar with most if not all of your publications and I learned a lot from them.

I do remember that in one of your papers you made a big effort to build a low impedance current transformer using a number of toroids. In the following paper you switched to using a binocular type of output transformer. I tried both approaches and did not find any appreciable difference.

I see some contradiction in your statements below. While the low impedance will clearly be the case at the low frequencies, the opposite would happen at the higher frequencies where the reactance shoots up very rapidly. Does this mean that it would be easier to build a transformer for the higher frequencies where there is a lot of inductive reactance?? When building a transformer should we take into account the inductive reactance at the highest frequency to calculate the number of turns or not??? If the reactance in a closed loop (short circuit) is indeed intact and not suppressed then it would be rather difficult to build a transformer that can cover the full range from say 1.8 Mhz up to 28 Mhz. What is your opinion on covering the full range with one broadband loop antenna and by covering I mean really being able to receive weak amateur stations as well and not broadcast stations. Some even claim that their antennas work up to the FM band and even higher.

All commercial broadband loop manufacturers claim a very large bandwidth from far below 1Mhz up to 30 Mhz and even higher. My findings are that the signal strength goes down substantially at frequencies over 7 Mhz . 14 Mhz is still doable but much at much higher frequencies my little flag antenna wins every time.

In my experiments I make use of three different amplifiers. The first one is a low input common base, the second is a differential amplifier with higher input Z and the third one is a two stage Norton amplifier with 50 ohms input Z. For my frequency range of interest 7 -28 Mhz) I would say that the differential amplifier works best for this range.

Transmission and reception place very different requirements on an antenna. The property that affects the transmitting antenna the most is efficiency. That comes down to size. Efficiency is the ratio of the radiation resistance to the sum of the radiation resistance and the loss resistance. The equation for radiation resistance uses the fourth power of the ratio of the antenna diameter to the wavelength. So no matter how much you work to reduce the loss resistance it is very hard to overcome that fourth power of the size.

I would expect a Mobius loop antenna to be very difficult to construct from similar materials to standard loop antennas; 1 to 3 inch copper tubing. I have read where heliax is sometimes used for loops. This might make a reasonable Mobius loop antenna, but I can't see how it would perform significantly better than a standard loop.

Rick

More precisely, the radiation resistance is proportional
to the area squared. For transmitting antennas, it is
so critical that the shape of the loop is even a consideration.
The area of a square that will fit inside a circle is 2/pi
times the area of the circle. Thus the radiation resistance
is reduced by a factor of 4/(pi squared) = 0.405. If the
ohmic loss dominates, that's a 4 dB decrease in gain.

Area is also everything when it comes to bandwidth.
If you want to transmit with a loop, make it really big
(in terms of wavelength) and just use wire (or maybe the
outer conductor of RG-6 coax). I realize doing this is
very boring and won't impress anyone with your photos
of 4 inch copper tubing or helical windings. It will
just work on the air.

Jef, your first sentence is quite correct. See
http://www.wellbrook.uk.com/pdf/ALA1530AntennaFactorChart.pdf

In fact the ALA1530 sensitivity is higher above 14MHz.

With the flag antenna the gain increases by 6dB per octave. This is due to an increase in radiation resistance with frequency compared to the loss with the termination resistance. At low frequencies one has to consider that the termination resistance of the Flag is a 3dB noise source. This is a significant factor when trying to make the antenna small in relation to wavelength.

Good morning Andrew,

Thanks for your comments. I actually got an ALA 1530 some months ago but have not installed the antenna yet. I am very happy to hear that it’s sensitivity should go up at the higher frequencies.
What it means is that my own home brew loop is still not on par with the big boys but I am learning and I am well aware of some of your work.
Best regards,

Jef

11350. Transmitting with a shielded loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-03-22 15:47:53 UTC
From: John Seager
Topic: 11350 Message: 11350

(Note altered thread).Chris kindly responded to the question of whether shielding a small loopmight have any advantages when used for transmission by saying it'might'. That raises a question as to how. The Moebius antenna,effectively a 2 turn loop will increase resistance loss, a notably dumb thingto do in the case of a small loop.A shielded loop might alter the effect of ground proximity and perhaps thatmight be of benefit in some situations. I wonder what the effect of a shield might be on loop resonance?Rick's point that a large wire loop is best of all is certainly true, but the factis that small loops work well and the interest here is just to see if a little morecan be coaxed out of them...73 John G0UCP

I think antenna design is often overly simplified. Suggesting that the loss resistance increase of using a two turn loop is a bad thing is not looking at the full picture. If increasing loss resistance were automatically a bad thing, large loops would never be used. Even if you only add a second turn to a loop antenna, the loss resistance doubles, but the radiation resistance quadruples which improves the efficiency. So increasing the loss resistance is not such a dumb thing to do really. The issue is *how* you do it and what you get in return.

What is the point? Very compact transmit loops need as much conductivity as you can get, adding a shield would not help one bit. The efficiency of a TX loop is proportional to the amount of copper in the SINGLE turn, if you increase the surface area or run several parallel tubes then the efficiency improves as you reduce the loss resistance . Shielding the structure would greatly reduce the tuning range by adding distributed capacitance around the loop, then there is the issue of insulating the shield..... does not seem to be sensible.

(note please don’t hang small weights to loops to increase their weight – that is not what was meant!!)

On the other hand if you have the space for a quarter wave around loop I.e. 10 m square sides for 160m you can make an Edgington Loop out of hook up wire. No shield used. If you scale this loop down for 30-10m it becomes very compact and very much cheaper to make than a conventional “”Magnetic”” antenna.

Receive is completely different , you need good balance to minimise noise sensitivity, a shield CAN help but is not essential in most cases.

Making a small loop out of a very fat conductor results in an
astronomical Q. Although the theoretical efficiency of the
loop itself might be decent, the high Q will cause the matching
network to be lossy, and you still get low efficiency. If you somehow
overcame this obstacle, the bandwidth would be impractically narrow.

Yes, if you make the loop circumference 1/4 wavelength, it actually
starts to work as a transmit antenna, although the bandwidth will
still be narrow if it's efficient. Loops this large are not
"magnetic" loops in the sense of emanating pure magnetic fields.
Rather, they are more like short bent dipoles. They have a very
shallow null broadside, which is probably good if you are transmitting.
The current around the loop is not uniform.

Edginton (there is no "g" in his name) mentions that his 1/4 wave
160 meter loop is 1/2 wave on 80 meters, and thus hard to drive
because the impedance is very high; IE it is parallel resonant.
He neglects to mention that there is a very simple fix for this.
Just open the loop at the midpoint away from the feedpoint.
Now it is basically a bent 1/2 wave dipole. No
problem at all. Of course this dipole will work better if you
don't bend the ends so much that they almost touch.

Sorry for the typo in Ben Edginton’s name. If you would like to see the Edginton Loop have a look at : g0cwt.co.uk/magloops. The loop is a quarterwave of thin wire with a series tuning capacitor and a ferrite transformer next to the tuning capacitor. I had read about it in Radcom one month then forgotten all about it. One night I received a very good 160m WSPR signal from Texas in the UK, an email then said it was an Edginton Loop 40’ wide.

Good luck and goodbye.

I see Edginton has a patent on his loop. Reading the patent I can't see what aspects are particularly patentable. He seems to list the fact that it is portable as well as using "multi core" wire. Was any of that new in 1995? I've seen photos of loop antennas from the early part of the 20th century.

One thing I have learned about loop antennas more recently that the huge emphasis on low loss construction methods is not at all important if the size of the loop is increased adequately. In other words, if you can use a large loop in relation to the wavelength, it can be wire rather than copper tubing. That seems to be what his antenna is about, but that surely wasn't remotely new in 1995.

I think it was the transformer coupling, though the late C.F. Rockey, W9SCH had described something remarkably similar in 1989 (Sprat No. 60). Patents are curious things. John

I think the patent was a pretty inconsequential lightweight one anyway. The main novelty was encapsulated in principal Claim 1 pertaining to the xfmr feed and matching arrangement, the remainder dependent claims are quite trivial. But even the transformer feed method has copious prior art.

As Rick N6RK said in an earlier post the large quarter-wave loop circumference deviates substantially from magnetic loop mode; being instead a bent folded-up short dipole with added lumped capacitance to achieve resonance. The thin conductor wire structures are not classical small magnetic loop radiators exhibiting substantially uniform current, but nevertheless radiate well, have usefully wide VSWR bandwidth, and give good accounts of themselves for DX if orientated in the direction of their principal pattern lobe.

Francis,
For many years I ran with a diamond shaped horizontal full wave loop on 40m SSB at 20ft above the back lawn using 5 watts from a very old Trio TS-130V and had great fun working the world.

I tried numerous feedlines from 1/4 wave 75 ohm co-ax, 120 ohm twin line, simple loudspeaker cable, 300 ohm ribbon line and homebrew 600 ohm but finally settled on no feedline just running the ends of the loop to the rear of a SO-239 socket on a wall panel and a 3ft 75 ohm co-ax patch lead to the rig.

Over the years I had numerous ‘ static clouts ‘ whilst unplugging the lead in stormy wx so got into the habit of letting go the mast halyard and letting the antenna lie on the grass.
Under such conditions I have seen static sparking between the centre and body of the SO-239 socket so beware.

Good luck with the trials.
Regards,
72, Brian, GØNSL.

Hi Francis,

If you will look in the file section on this group you will find a article that
I posted "Loop Balun Experiment". In the article I looked at different baluns
on my 275' Horizontal loop. Using a 4:1 current balun I have band coverage
on all bands from 80 through 6 meters, including the WARC bands, with the exception of 60
meters.

I am using about 100' of RG-8X coax from the antenna to my shack
and have the coax shield grounded just before it enters the house. This
eliminates any static build up on the antenna. I do use my K3S antenna
tuner if I want to operate on 75 meters.

If you really want this to work, it should be
done in two stages. A 1:1 current balun
using a ferrite-loaded transmission line.
(Preferably a large ferrite toroid with multiple
turns of coax, rather than the markedly
inferior string of beads around the coax).
The 4:1 impedance transformation should be
done separately, preferably with a Ruthroff
type (not a Guanella) transmission line
transformer using 100 ohm transmission
line for the windings. Series
peaking capacitors can be added to extend
the low frequency range and parallel peaking
capacitors can be added to extend the
high frequency range.

Common Mode Currents do not seam to be a problem with a horizontal loop. I have no RFI issues, however, I do use a 4:1 home brew current balun using dual cores with 10 bifilar turns on each.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11373. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-04-01 13:08:20 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11373

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11377. Ferrite Sleeve Loop

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-04-09 03:27:07 UTC
From: hmholden69@...
Topic: 11377 Message: 11377

I am a MW Dxer and have been reading about a relatively new type of loop called a Ferrite Sleeve Loop. It seems to be several ferrite rods or bars mounted around a central round form and then overwound with litz wire to form a coil that is connected to a variable capacitor to get resonance. The thing kind of looks like a gatlin gun. Most of these I have read about are usually just inductively coupled to a loopstick in a radio and seem to give performance equal to or better than a 4 foot box loop but in a more compact package. I am interested in building one of these but want to feed directly to a communications receiver that has no internal loop stick. Has anyone had any experience in doing this? I'm thinking you would have to wind a one or two turn coupling link next to the main coil.

11378. Re: [loopantennas] Ferrite Sleeve Loop

From: Brian
Topic: 11377 Message: 11378

Hi,
Whilst not giving you ‘ chapter & verse’ on the subject
put ‘ Ferrite sleeve loop antennas ‘ in Google, then when the hits appear click on
‘ images ‘ at the top, the many pictures will give you ideas and if you want to know more
click on the adjacent photo website.

I find this method gives a good overall coverage whatever the subject.

Regards,
72, Brian, GØNSL.

I think maybe if you place a 1:1 or 4:1 balun transformer between the loop and receiver, the secondary coil of the balun (the coil connected to the receiver), should take the place of the missing internal loopstick.

You can couple up to a FSL, using a 1 turn coil. The coil is connected to a matching transformer, which is made using a ferrite binocular core BN73-202, with with 2 turns wound on the 50 ohm side and 16 turns on the coupling loop side.

This works well without killing the Q of the tank circuit. This same matching transformer also works very well with air coil tuned loops.

It seems to be several ferrite rods or bars mounted around a central round form and then overwound with litz wire to form a coil that is connected to a variable capacitor to get resonance. The thing kind of looks like a gatlin gun. Most of these I have read about are usually just inductively coupled to a loopstick in a radio and seem to give performance equal to or better than a 4 foot box loop but in a more compact package. I am interested in building one of these but want to feed directly to a communications receiver that has no internal loop stick. Has anyone had any experience in doing this? I'm thinking you would have to wind a one or two turn coupling link next to the main coil.

I was wondering if anyone could share a generic loop antenna amplifier schematic. I would like to try my hand at building one if possible. Something similiar to lets say the wellbrook ala-100 or such. Does anything exist like this?? I recently built an e field probe mini whip antenna and I like it very much. I just can't get enough wire in the air for a good passive antenna due to not enough real estate.
Thank you, John in fla

Thanks for the info on the coupling transformer. I have ordered some of those binocular cores and will have a go at winding it. I want to try on a 3 foot box loop that has a one turn coupling loop. I will use the 8:1 winding ratio you suggested and attach that to the one turn coupling link. If I remember correctly the square root of the transformer winding ratio gives the impedance ratio.

I posted such an amplifier in the files section almost six years ago:

WidebandLoopAntennaAmplifierRevA.pdf

It's a bit ambitious, but has performance at least equal to that of the Wellbrook.

Back when I first looked into wideband active loops, I learned by way of EZNEC that the radiation pattern deteriorated quickly as the terminal impedance was increased. It made sense when considering that the loop antenna is a current source, not a voltage source. This made the design of the amplifier very simple as no matching network was needed, just a low input impedance amplifier.

Since the input impedance is very low, Wouldn't that suggest that only strong signals would get amplified and that the antenna wouldn't be sensitive enough to be driven
Properly with weak signals? Or does only pertain to voltage type Amplifiers? Thanks John

Rick, at low frequencies a small loop is a low impedance current source and hence, the best impedance match would be an amplifier with a similar input z. As the frequency increases, the loop impedance increases, so there is a miss-match with the low impedance amplifier. However, the loss due to loop/amp. miss-match is compensated by the increase loop output power because the radiation resistance increases with rising frequency. This feature effectively means that the loop/amp. will provide a constant Antenna Factor verses frequency. This is how most broadband loops work.

This may be a bit confusing, so I'll try to remember to sign my posts as Rick C.

Antenna Factor with a fixed impedance receiver input of 50 ohms is defined as AF = 9.73 / (Lambda * G) where G is the antenna gain.

This formula accounts for the impedance mismatch between the antenna and receiver. So the AF still varies with frequency. Using a receiver with even lower input impedance than 50 ohms only changes the constant from 9.73 to another, higher value. Antenna Gain is a function of the radiation pattern and not related to the radiation resistance. As long as the antenna size is small compared to lambda the gain will not vary much.

By definition the antenna factor always changes with frequency.

Rick C.

I have a hard time grasping the theory of impedance. Here's a question I have for the group or anyone who wishes to answer it. Why in a crystal radio set is it better to have high impedance headphones vs. low impedance headphones to hear the signal. Wouldn't the low impedance headphones allow for the tiny signal to pass easier, where as the high impedance would block the signal? I know it's a stupid question, but I wish someone could explain impedance in layman's terms.

Good morning Andrew, Chavdar,

I fully understand the theory and logic of using a low Z and more so when you are talking about the lower frequencies. The various low Z amplifiers that I built all give very, very strong signals at the lower frequencies up to and including the 7 Mhz band. However at 14 Mhz the signal strength tends to go down and at 21 and 28 Mhz there is a very serious reduction in signal strength. Yes I can copy stations and the big guns in the CB band at 27.025 Mhz from California are loud (S 9) in Florida and so are the various AM broadcast stations. Lower power amateurs in the higher bands are however disappointing and are much easier to receive with a flag antenna that I have in the attic.
The only logic I see here is that the impedance goes up much faster than the increase in radiation resistance. Chris Trask in his papers shows a graph of the impedance increase which shows a very steep increase around 14 Mhz which seems to confirm my own findings. I think that it is very unlikely that you get a constant antenna factor up to 30Mhz with a low Z amplifier. Whether this is due to various resonances I do not know.
To receive amateur stations in the 14Mhz up to 28Mhz bands I get much better results by using a differential amplifier with a much higher Z and by using a 4:1 input balun in order to reduce the impedance at the loop ends. Using an MFJ antenna analyzer I do get values of some 200 -350 ohms impedance at the loop ends over the frequency range from 14-28Mhz.
BTW I am using a 90cm diameter low impedance loop (alu strip of 1 inch). The inductance of the loop measured with an LC meter gave me a value of 1.7 microhenry.
Anyway I am having fun with these loops,

Jef

In the case of the headphones you are trying to maximize the power into the headphones. In this case "high" is relative and 600 ohms would be considered "high" impedance. Using a lower impedance would mostly drag down the voltage on the output resulting in less power being transferred to the headphones.

It is easy to show you get the maximum power transferred into a load if you use a load that matches the impedance of the source. The issue is not current or voltage, but the product of the two. Too high an impedance and the current drops too much, too low an impedance and the voltage drops too much.

Rick C.

Dear Rick C,

My post was in reply to Richard Karlquist.

You say that “Antenna Gain is a function of the radiation pattern and not related to the radiation resistance”. I don’t agree with this statement; because the gain seen in the radiation pattern is due to the antennas radiation resistance.

With regard to wideband active loop antennas; generally the A F is constant within a few dB over most of the design bandwidth. This statement is based an calibration data provided by Mectronics Marine in the UK who calibrate some of my loop antennas.

Kind regards

Andrew

Subject: Re: [loopantennas] Re: Schematic for loop amplifier

This may be a bit confusing, so I'll try to remember to sign my posts as Rick C.

Antenna Factor with a fixed impedance receiver input of 50 ohms is defined as AF = 9.73 / (Lambda * G) where G is the antenna gain.

This formula accounts for the impedance mismatch between the antenna and receiver. So the AF still varies with frequency. Using a receiver with even lower input impedance than 50 ohms only changes the constant from 9.73 to another, higher value. Antenna Gain is a function of the radiation pattern and not related to the radiation resistance. As long as the antenna size is small compared to lambda the gain will not vary much.

By definition the antenna factor always changes with frequency.

Rick C.

Factoring in capacitance and inductance is why it's called impedance rather than resistance. Don't worry so much about the details of what is going on with the capacitance and inductance, it's all factored into the definition of impedance. Pick a frequency and it's very similar to resistance.... unless you hit a resonance point.

Jef,

I can’t comment on Chavdar’s antenna design because I haven’t used it. With the Wellbrook loops the amplifier input Z is set by using negative feedback. Hence, it is possible to set the input Z to raise with an increase with the loops reactive with frequency to minimise the loop/amp. miss-match verse frequency. In fact I do have a loop prototype loop amp. that perfectly tracks a 1m loop Z from 0.5MHz to 30MHz. However, the 2dB improvement in the HF sensitivity compared to the ALA1530 doesn’t warrant the additional complexity. Also the ALA1530 has now been overtaken by the FET LN versions which offer much better performance and amp. noise figures of less than 0.2dB.

Lower power amateurs in the higher bands are however disappointing and are much easier to receive with a flag antenna that I have in the attic.

The only logic I see here is that the impedance goes up much faster than the increase in radiation resistance. Chris Trask in his papers shows a graph of the impedance increase which shows a very steep increase around 14 Mhz which seems to confirm my own findings. I think that it is very unlikely that you get a constant antenna factor up to 30Mhz with a low Z amplifier. Whether this is due to various resonances I do not know.

To receive amateur stations in the 14Mhz up to 28Mhz bands I get much better results by using a differential amplifier with a much higher Z and by using a 4:1 input balun in order to reduce the impedance at the loop ends. Using an MFJ antenna analyzer I do get values of some 200 -350 ohms impedance at the loop ends over the frequency range from 14-28Mhz.

BTW I am using a 90cm diameter low impedance loop (alu strip of 1 inch). The inductance of the loop measured with an LC meter gave me a value of 1.7 microhenry.

Anyway I am having fun with these loops,

Jef

Why does the input impedance need to be very low?>

Rick, at low frequencies a small loop is a low impedance current source and hence, the best impedance match would be an amplifier with a similar input z. As the frequency increases, the loop impedance increases, so there is a miss-match with the low impedance amplifier. However, the loss due to loop/amp. miss-match is compensated by the increase loop output power because the radiation resistance increases with rising frequency. This feature effectively means that the loop/amp. will provide a constant Antenna Factor verses frequency. This is how most broadband loops work.

Hi to Rick and ……
Loop Amplifier
The low impedance load to a small loop is needed to achieve flat wideband response. The loop must work almost in short circuit mode. If the loop is small, its current is calculated simply by the Faraday's law where the short circuit current does not depends on frequency. I am not a professional in antennas and I cannot make easily link between Faraday law and antenna gain . Also we do not need to assume the radiation resistance – it is so small that it does influences at all the loop current. I think that the theory is very simple until the loop perimeter is much shorter than the wavelength.
In my spice models of the amplifier, the loop is represented as a frequency independent current source and it is a good approximation above certain frequency. The upper frequency limit is up to where the transmission line effects cannot be ignored. The loop amplifier is a current to voltage transducer. There is no impedance matching . The Low-Z wideband loop amplifier is just complementary to Hi-Z short dipole (whip) wideband amplifier.
The main problem is whether we can achieve amplifier noise floor which is below the atmospheric noise level in this particular case. My own observations is that this is possible up to 15 – 20 MHz . On higher bands, in quiet rural locations, the atmospheric noise is very low. There the active loop sensitivity is limited by the amplifier internal noise. So there we must use loops with higher short circuit current. One solution is to use crossed coplanar loops where we can increase loop current and preserve at the same time small loop pattern and to have sharp nulls for the local noise sources.
The common base balanced amplifier that I am using is one of the active wideband loop solutions. It has approximately 6 ohms input impedance and will give flat response above 150 KHz with loop inductance in order of 2 to 4 uH. An amplifier with 50 ohms input will be flat above 1.5 MHz. The very low input impedance has another benefit – there is no need to use shielded loop since the loop is very well balanced with sharp and symmetric null.
Other designs might reduce the active antenna noise floor further on. One possible solution is to have an amplifier whose input impedance is always e.g. one tenth of the loop impedance. That means the amplifier must have linearly increasing input impedance with frequency. Thus we will have 10 % impedance matching in the total bandwidth, preserving the flat frequency response at the same time. This will be not bad for a wideband RX antenna.
For those who are interested in details about these topics look at www.lz1aq.signacor.com .

Crystal Radio
The answer is again an impedance matching. The crystal radio output impedance is high - equal to the equivalent resistance of a the high Q parallel circuit loaded with the antenna impedance. I remember in my childhood (I was 10 years old when I made my first crystal radio) , the high impedance earphones were in order of 4000 ohms which was probably near to the crystal detector impedance. This is almost the same problem as in the active loop.
Active loop is equivalent to a crystal radio loaded with 6 ohms earphones J

Probably the easiest way to visualize impedance matching is to use an analogy with a direct current circuit. Think of the antenna as being a source of electrical current...like a 1.5 volt battery. Then think of the headphones as being a load across the battery such as a resistor.

The battery cannot supply an unlimited amount of current. for example, ohms law would tell us that if you place a 1.5 ohm resistor across the battery
you would get one amp of current. But we know that we will not get that much current from a 1.5V triple a cell. This is because the battery has an internal resistance
that limits the amount of current you can get out of it.

Now lets look at a case where a very high resistance is placed across the battery...one million ohms. Without doing the math, we know that the current being drawn from the battery is going to be very small...nowhere near what the battery can supply.

So it stands to reason that there is an optimum value of resistor that we can place across the battery that will ensure the greatest amount of " POWER" (voltage X current) will be transferred from the battery to the resistor.

Likewise, the crystal radio is a very high impedance (Like high internal resistance) and it can only supply a very small amount of current. Therefore the headphones must also be very high impedance (like the resistor) so that the most
amount of power can be transferred from the radio to the phones.

I hope this helps....it sure helped me when I was studying this stuff.

Regards..Steve VE9SF

> I have a hard time grasping the theory of impedance. Here's a question I have for the group or anyone who wishes to answer it. Why in a crystal radio set is it better to have high impedance headphones vs. low impedance headphones to hear the signal. Wouldn't the low impedance headphones allow for the tiny signal to pass easier, where as the high impedance would block the signal? I know it's a stupid question, but I wish someone could explain impedance in layman's terms.

Thanks Andrew,

Your explanation is clear now and makes sense. I have seen amplifiers where they use inductors in the emitter which indeed should raise the Z in at higher frequencies. I will give that approach a shot before I jump on the Fet approach. This will keep me busy for a while…

Jef,

I can’t comment on Chavdar’s antenna design because I haven’t used it. With the Wellbrook loops the amplifier input Z is set by using negative feedback. Hence, it is possible to set the input Z to raise with an increase with the loops reactive with frequency to minimise the loop/amp. miss-match verse frequency. In fact I do have a loop prototype loop amp. that perfectly tracks a 1m loop Z from 0.5MHz to 30MHz. However, the 2dB improvement in the HF sensitivity compared to the ALA1530 doesn’t warrant the additional complexity. Also the ALA1530 has now been overtaken by the FET LN versions which offer much better performance and amp. noise figures of less than 0.2dB.

Good morning Andrew, Chavdar,
I fully understand the theory and logic of using a low Z and more so when you are talking about the lower frequencies. The various low Z amplifiers that I built all give very, very strong signals at the lower frequencies up to and including the 7 Mhz band. However at 14 Mhz the signal strength tends to go down and at 21 and 28 Mhz there is a very serious reduction in signal strength. Yes I can copy stations and the big guns in the CB band at 27.025 Mhz from California are loud (S 9) in Florida and so are the various AM broadcast stations. Lower power amateurs in the higher bands are however disappointing and are much easier to receive with a flag antenna that I have in the attic.
The only logic I see here is that the impedance goes up much faster than the increase in radiation resistance. Chris Trask in his papers shows a graph of the impedance increase which shows a very steep increase around 14 Mhz which seems to confirm my own findings. I

Hi Jef,
You (and Chris) are right that above certain frequency the loop is not small and begin to act as a normal antenna and the “simple” loop theory does not work anymore. Single 1 m loop at 20 MHz has almost wl/4 perimeter. Its polarization pattern is quite different with strong horizontal component and probably it needs height to have sufficient sensitivity.
Have you tested crossed coplanar loops? If you make another 1m diam. loop and connect both as described in my article you probably will have the following:
- The signal level will increase with 4 -5 dB (theoretically 6 dB).
- The loop pattern will be as a small loop up to 50 Mhz.
- The loop will have also at higher frequencies sharp nulls for local vertically polarized noise.
- The crossed loop inductance will be almost twice lower.
- But in order to benefit from the crossed loops, the input impedance of the amplifier must be several times lower than the loop impedance. The idea is to have two current sources which are added into common load (the amp. input) . Otherwise the loop currents begin to flow between both loops, not into the amplifier input. In this case you might get better results with a single loop with the same total area. I cannot predict what will be the impedance of these crossed loops at higher frequencies and any feedback is welcome.
- For experiments you can use a wideband input transformer to lower the input impedance of an ordinary 50 ohms amplifier in order to fulfill the requirements for the crossed loops.
Have a fun,
Chavdar lz1aq@abv.bg

Good afternoon Chavdar,

Thank you so much for your clear explanation. I do find indeed that using input transformers is one way to make the loop respond to higher or lower frequencies. I have experimented with crossed loops as well with variable results but that was most likely due to the fact that I did not get the understanding of what is really happening in a loop with the inductance when you operate the loop in short circuit mode. But I am learning and I see progress almost every week.
Thanks also to Andrew Ikin and KCOG for explaining us the way forward.

Jef

WL1030 by the late Maartenhagg. Plans placed on this website by his friends in his honor.
http://wl1030.com/content/

C Crane Company
They sell the Justice AM Loop Antenna, Select A Tenna, Terk AM 1000
http://www.ccrane.com

Kiwa Electronics
Kwia makes the best products for you and your radio equipment, and also improves things that needed improvement a long time ago.
http://www.kiwa.com

Stormwise Ferrite Rods
Get some huge ferrite rods and a converter to go along with its, heck it even comes with project book.
http://www.stormwise.com

Universal Radio Company
They sell all sorts of loops big and small for LW/MW/SW and VLF also 10 kHz to 15 MHz
http://www.rffun.com

ALA-1530
Find the best UK LF/MF antenna here.
http://www.wellbrook.uk.com/

AOR
This is the site that sells the AOR loop
http://www.aorja.com/ant-e.html

Kiwa Electronics
The maker of the air core loop antenna and other useful items that you may want on your wish list.
http://www.kiwa.com

LF Engineering Company
A group of engineers, who make products for VLF/LF listening even ELF loops!
http://www.lfengineering.com

Select A Tenna by Intensitronics Corp
The maker of the select A tenna, a great AM loop antenna that is a little bigger than the terk
discontinued

Terk Technolegies
The maker of the best sold AM and I use also called the AM-1000 AM loop antenna, there is also technical information on how it works.
http://www.terk.com

Torus Tuner Loop Company
A very specially made loop that is almost as big as a hula hoop
discontinued

GRAHN (Germany) Specialized Loop Antennas for MW and SW Reception Contributed by radiohighfreq
Grahn offers both Ferrite Rod Antennas and Shielded Loop Antennas. Translated from the Gremany Language Webpages here is the "Grahn Specialized Loop Antennas for MW and SW Reception" ULR Address: http://www.grahn-spezialantennen.de/
Use the Google Translate a web Page Tool http://www.google.com/language_tools to convert these webpages to English.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11411. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-05-01 13:29:10 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11411

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11412. PVC self standing frame for loops - any plans?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-05-01 20:54:25 UTC
From: ktjensen1994@...
Topic: 11412 Message: 11412

Does anyone have some simple plans for a PVC frame that can be built cheap to start experimenting with loop antennas? Just need a cookie cutter approach instructions if that's possible.

N1KTJ

11413. MFJ-9232 any discussion?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-05-01 20:57:00 UTC
From: ktjensen1994@...
Topic: 11413 Message: 11413

Has anyone made good use of the MFJ 9232 loop antenna capacitor? I am considering it because of the price. Will likely switch to copper tubing instead of the included wire with it. Sure its QRP power but the price of $60 can't be beat compared to almost anything else.

11414. Re: [loopantennas] MFJ-9232 any discussion?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-05-02 05:04:23 UTC
From: vk2tti@...
Topic: 11413 Message: 11414

G'day kj, regarding the MFJ9232 loop tuner. I've had one for about six months. You get what you pay for. I am pleased with my purchase. Tuneing and matching is very course, no fine tuneing available. For receiving its no problem when tuneing by ear. However when using an antenna analyser the courseness of adjustment can be frustrating. I bought the device to use with an FT817 and for SWL. Hand capacitane don't seem to present a problem. A large copper pipe loop would need extra support, the loop tuner has only a small footprint, it would be unstable. Hope this helps, Regards Max vk2tti.
PS I also have an MFJ-936B, it won't fit in my pocket like the 9232.

Go to Lowe's or Home Depot and look for PEX pipe. It is a polyethylene pipe and can easily be formed into a circle. Get it in either 3/4" or 1". Also look at electrical junction boxes to use as a base for the loop. Then you can either put a wire, or coax inside for the loop.

yes it would be indoors. I am thinking of the MFJ-935B to buy. Just need a way to get it all stable and mounted. Sure the loop will have a PVC frame as they suggest, but then the whole assemble together seems so wobbly and flimsy.

Am thinking about a simple mount of the MFJ-935B to a plastic portable table. Or thinking of a mount of that unit to a camera tripod with a quick connect foot. Do not know if I have seen a MFJ-935B on a camera tripod mount yet, but that may be because the tripod would detune the loop.

Thanks Maxwell. You cleared that up for me. that the fine tuning needed is not possible with the small portable, and that I would be in for some frustration if I was trying to hit a specific frequency. That's exactly what I would be doing. Trying to get the exact frequency I need for JT65 operation. If I can't hit that frequency I am stuck with no solution.

Will avoid this one then, and go for the $200 solution.

G'day kj, I've had a 936B for some time and have been happy with it. Loop antennas have a directional property. I place the radio and battery on a "lazy susan", on top of the radio I place the loop tuner, on top of the tuner I place the indoor antenna. The whole setup can be rotated to advantage. Max vk2tti. PS one of the blokes at the Men's Shed said he had a lazy susan be he divorced her Hi Hi.

If you want to use PEX there is a type that has a layer of aluminum between two layers of PEX. It is called "PEX-AL-PEX". The purpose is to keep oxygen out of a heating system. It is sold for floor mounted heating systems. With the aluminum layer it should be stiffer than plain plastic tubing.

By using this you can run your wires through the tubing with the PEX giving you some spacing from the aluminum to reduce the capacitance and you get a shielded loop which is good for reception! You would need to remove some of the outer layer of the PEX in the middle of the loop to make a ground connection and a hole to bring your wires out for the loop.

Or are you building a transmitting loop?

Rick C.

From: Leigh Turner
Topic: 11381 Message: 11423

This discussion thread is a very interesting one.

For typical MF/HF ham band use I cannot see the virtue of wideband active Rx loops; in a past life I used to design and deploy carefully balanced Rx loops (TEMPEST and covert ELINT intelligence signals gathering / SIGINT stuff for certain unmentionable government agencies) with extremely high common-mode rejection ratios and reduction in E-field sensitivity. Some of these Rx antennas were active loops tuned using wide capacitance range / hyper-abrupt junction high-Q variable capacitance / semiconductor varactor diodes for remotely tuning the loop in combination with a wide dynamic range unity-gain FET buffer to transform the resultant high dynamic parallel impedance down to 50 Ohm.

This circuit configuration achieves an extraordinarily high power gain due to the Q-multiplied open-circuit signal voltage across the high impedance loop gap being transformed to nearly the same voltage across a 50 Ohm load. Of particularly significance however is the dramatic gain in SNR / sensitivity resulting from the "swamping" of the FET thermal KTB input noise by the Q-gain (say 400) of the tuned loop circuit; a dramatic level of improvement unobtainable from the alternative combined use of a passive matching network and a low-noise amplifier or Racal / Harris receiver with an equivalent input noise of 50 Ohms (3 dB noise figure). The technique works well from VLF thro' to HF and will detect weak signals previously thought to be irretrievable from the prevailing environmental noise.

Unlike overload and spur vulnerable wideband loops you don't need a pre-amp with a very high intercept IP3 if you do the feed impedance translation, and exploit the loop's natural high Q and selectivity and deep polar pattern nulls to reject local noise sources.

This is a neat way to simultaneously achieve an ultra low noise floor and wide dynamic range / intercept point. There's a penalty to be paid for an un-tuned wideband loop; besides tuning to resonance is no big deal if it's done electronically by cranking a pot to set the varactor voltage. The resultant high-Q pre-selector bandpass filter on the Rx front-end can help a lot. The external atmospheric noise will always dominate that of the KTB noise floor of the loop's internal active circuitry; even up at 30 MHz.

Symmetry and balance is always very important if you want to exploit the Rx loop's potentially excellent noise / QRM rejection properties.

Balanced and rotatable small HF loop antennas are also effective at greatly reducing the reception of such localized man-made noise in the lower HF bands. The "low impedance" of the loop structure dramatically reduces man-made noise from being received by the electrostatic induction mode which

often renders "high impedance" dipoles and monopoles useless for weak signal detection in congested urban locations. The main ingredient of local man made noise is quasi-static electric field energy which decays rapidly with distance. As the impedance the magnetic H-field responsive loop presents to an incoming signal is very low compared to a dipole, its balance with respect to ground tends to be preserved whereas the high impedance ends of the dipole are easily disturbed by any inevitable asymmetry in the local environment. Of course a vertical monopole or whip is the most susceptible of all antenna types to man made noise; its susceptibility exacerbated by a typical ground plane of limited size or conductivity. Below say 5 MHz, SNR differences / improvements of 30 dB or more are not uncommon when comparing a good balanced H-field loop to an E-field responsive vertical whip!

An interesting design to contemplate might be to combine broadband and tuned designs into a switchable circuit. A single loop element would be switched between a broadband amp and a varactor-tuned amp. Broadband mode could be used for band scanning while tuned mode could be used to dig out weak signals or combat strong co-channel interference and mitigate QRM.

With such switching the loop between broadband and varactor-tuned modes one can achieve the best of both worlds and be able to exploit their relative merits as the particular need arises.

You'll notice quite a difference in antenna and SNR performance in the tuned loop mode...

Hope forum readers find this interesting and inspiring to try the concepts.

Cheers,

Leigh

Subject: Re: [loopantennas] Re: Schematic for loop amplifier

Jef,

I can□t comment on Chavdar□s antenna design because I haven□t used it. With the Wellbrook loops the amplifier input Z is set by using negative feedback. Hence, it is possible to set the input Z to raise with an increase with the loops reactive with frequency to minimise the loop/amp. Miss-match verse frequency. In fact I do have a loop prototype loop amp. That perfectly tracks a 1m loop Z from 0.5MHz to 30MHz. However, the 2dB improvement in the HF sensitivity compared to the ALA1530 doesn□t warrant the additional complexity. Also the ALA1530 has now been overtaken by the FET LN versions which offer much better performance and amp. Noise figures of less than 0.2dB.

Subject: RE: [loopantennas] Re: Schematic for loop amplifier

Good morning Andrew, Chavdar,

I fully understand the theory and logic of using a low Z and more so when you are talking about the lower frequencies. The various low Z amplifiers that I built all give very, very strong signals at the lower frequencies up to and including the 7 MHz band. However at 14 MHz the signal strength tends to go down and at 21 and 28 MHz there is a very serious reduction in signal strength. Yes I can copy stations and the big guns in the CB band at 27.025 MHz from California are loud (S 9) in Florida and so are the various AM broadcast stations. Lower power amateurs in the higher bands are however disappointing and are much easier to receive with a flag antenna that I have in the attic.

The only logic I see here is that the impedance goes up much faster than the increase in radiation resistance. Chris Trask in his papers shows a graph of the impedance increase which shows a very steep increase around 14 MHz which seems to confirm my own findings. I think that it is very unlikely that you get a constant antenna factor up to 30 MHz with a low Z amplifier. Whether this is due to various resonances I do not know.

To receive amateur stations in the 14 MHz up to 28 MHz bands I get much better results by using a differential amplifier with a much higher Z and by using a 4:1 input balun in order to reduce the impedance at the loop ends. Using an MFJ antenna analyzer I do get values of some 200-350 ohms impedance at the loop ends over the frequency range from 14-28 MHz.

BTW I am using a 90cm diameter low impedance loop (alu strip of 1 inch). The inductance of the loop measured with an LC meter gave me a value of 1.7 microhenry.

Anyway I am having fun with these loops,
Jef

Posted by: Chris Trask <christrask@...>

Back when I first looked into wideband active loops, I learned by way of EZNEC that the radiation pattern deteriorated quickly as the terminal impedance was increased. It made sense when considering that the loop antenna is a current source, not a voltage source. This made the design of the amplifier very simple as no matching network was needed, just a low input impedance amplifier.

Subject: Re: [loopantennas] Re: Schematic for loop amplifier

Rick wrote on April 27.

snip <The cited article states:

"This amplifier must be with very low input impedance."

Why does the input impedance need to be very low?>

Rick, at low frequencies a small loop is a low impedance current source and hence, the best impedance match would be an amplifier with a similar input z. As the frequency increases, the loop impedance increases, so there is a miss-match with the low impedance amplifier. However, the loss due to loop/amp miss-match is compensated by the increase loop output power because the radiation resistance increases with rising frequency. This feature effectively means that the loop/amp will provide a constant Antenna Factor verses frequency. This is how most broadband loops work.

Hi All
I have a MFJ935B that I use indoors. The lazy Susan is a great idea. If you go with copper tubing you will need a support for anything larger than about a five foot circumference loop. I made one from scratch, takes about 1/2 hour and about 5 dollars from home depot. I made a bracket to fit the pvc fitting on the top of the tuner and put a crosspiece in so that I could add support legs on each side of the tuner. On the top of the cross piece I have a long piece and a top support like a pvc inverted L. The loops are supported from the top using cable ties hooked to the top piece. The long vertical has two sets of couplings so I can make it the height needed for a 7 foot and a 10 foot circumference loop. I didnt use any plans, sketched out a rough plan and then needed to custom fit things. I have never been able to have pvc match the math, some fittings work great others always are either a little too long or short. Always get it right before cementing

Also. If you use a loop tuner, make sure you have it on a non-comductive surface otherwise you can detune it

G'day all. To work the lazy susan. Place an index mark on the moveing part of the susan. Rotate the structure to the point where you just lose the required signal. Place a finger or marker on the table top under the index mark. Rotate the structure through the point of maximum reception until you just lose the signal again. The point of maximum signal lies between your finger and the present position of the index mark on the susan. Regards to all Max vk2tti.

I don't recommend PVC pipe. Several reasons. (1) It is heavy - a large loop gets really heavy really fast. (2) PVC pipe is comparatively weak. Even six foot sections begin to sag with time. While it won't affect loop geometry that much, it is enough to let windings (external or internal) sag and lose their positioning. (3) if you use outdoors, PVC is really good at building up a static charge. Not something you want discharging / sparking into sensitive front ends!

Others have used Heliax in the past to make shielded loops. Seems to work okay, and the larger outer diameter will give you less bulk resistance losses, thereby increasing the Q and the efficiency.

Raoul,

FYI: Leigh Turner, VK5KLT, recently reported on two of the MLA's that
his good friend, Steve Adler, VK5SFA, in Adelaide, AU constructed using
1 17/64 inch Heliax.

Look at the conversations posted by VK5KLT as well as the QRZ.com
website of VK5SFA - who has a posted website , viz,:

http://members.iinet.net.au/~sadler@.../tmla.html

which contains a wealth of info and photos of the two-turn MLA's that
VK5SFA recently made - using heliax- which are working extremely well
on 160/80 and

40 meters.

11451. Magnetic Antenna - magic bullet for Apartment?

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-05-15 12:05:06 UTC
From: ktjensen1994@...
Topic: 11451 Message: 11451

So am looking for advice from others who live in apartments.

Have a nasty noise problem of S7 to S9 constant. Can not use any external antennas (no dipoles, no long wires). Have set up a temporary inside antenna in my third floor apartment, with endfed unun 9:1 and a long wire. It gets my reception of JT65 and I can decode.

The problem is I can do nothing else with my radio. Cant to CW, as I cant hear much anything else. Cant to Voice SSB. None of the bands work on anything else. Sure I can hear them slightly in the hash of noise, but can not interpret what they are saying at all.

Would a magnetic loop work as a solution? Am thinking of the MFJ-935B to try out and experiment with. Before I spend the money, I want to hear if others used magnetic loops as an apartment solution.

If you've got a balcony, get a loaded or tuned vertical and mount it somewhere on the balcony as far away from the walls. Otherwise, a tuned loop looks like a next step. Been there.....it was challenging to get even mediocre results pre-PC, 30+ years ago, and even worse today because of all the digital stuff. A.

From: Paul Stoetzer
Topic: 11451 Message: 11455

I've worked 161 DXCCs from the south facing balcony of my apartment in Washington, DC with magnetic loops: first an AlexLoop Walkham (106 DXCCs with that) and then an MFJ-1786 when I wanted to start running 100 watts. I had tried throwing wires over the balcony and such, but the magnetic loop definitely results in a better SNR on received signals.

Some great contacts include a 30m RTTY QSO with VK0EK.

The downside of magnetic loops, of course, is transmit efficiency. A really nice solution might be to use separate receive and transmit antennas.

Raoul CE3RY - yes I have thought about a noise canceling device like you mentioned. Its the same price as a magnetic loop, at around $200. So the choice is do I mess with noise canceling or do I mess with Magnetic loops. Eventually I am sure I will be into both.

11457. Re: [loopantennas] Re: Magnetic Antenna - magic bullet for Apartment?

Yahoo group: loopantennas (2013 — 2017)

Noise canceling works best when you have a single source of noise. If the noise is broadband power-line stuff (coming from every electrical thing connected to the power grid, and radiated by all power wiring), then your chances of success with that are marginal.

The other way to look at using one of the noise canceling units, is you are making a directional antenna array. By tweaking the unit's adjustment knobs, you direct a "null" in your antenna's pattern, in one particular direction, which is the interfering signal. Which is fine as long as all the noise is coming from that one direction. But if you have multiple noise sources, you are sunk using that method.

Regards,
Andy

11458. H or B Field Loop Antenna

I do not recall having seen something called an H-field or B-field antenna, but those terms refer to the magnetic field, as opposed to the electric field (the two components of electromagnetic radiation).

So I'm guessing that it means any electrically small loop antenna that responds mainly to the RF's magnetic field. I have seen many VLF loop antenna construction articles where the wire is wound around a ferrite rod to boost sensitivity. That would be one example. A few turns of wire wound around a wooden frame, or wound around a doorway, would be two more examples. Some LF/VLF/ELF antennas are short amplified whips, and that is not what this would be; they respond to the electric field.

Andy

Many years ago I had a signal tracer that was basically just a valve (tube) audio amp with high impedance input. It used to receive whistlers quite well with just a few inches of wire.

Cheers,

Will

G,Day all. I have had some good results in a suburban environment receiving BCB signals using two identical magnetic loops and a Quantum Phaser. The loops are mounted about a metre apart and parallel to each other with the phaser and radio in the middle.
Tune the loops individually, rotate the construction for maximum signal. Now rotate one loop so that you just lose the required signal but keep its noise.
Now both loops are immersed in the local noise and one is also receiving the distant noise arriving at both loops. The phaser when adjusted properly will yield up the required audio with both the distant and local noise removed . Regards vk2tti.

Adam, Way back in the70's and 80's, i used a 3 ft air wound loop with 70 or 80 turns of # 24 enameled copper. i heard lots of spherics but only heard whistlers once,(they're elusive anyway). Large ferrite loops ala Stormwise performed similarly. there are examples of H or B field antennas. You just connect them to a high gain audio amp. I used an old Archer mini amp from RS and got satisfactory performance. Then, in the early 90's, Conversion Research came out with their WR-3. It was a small E-field receiver that outperformed the magnetic field receivers and only used a small whip. They use a high impedance FET input that drives an LM386 8 pin IC amp on a chip, enough to drive a pair of earbuds quite well. Still use it to this day when camping. I've heard may a whistler since going "E". I also have an "Earth Monitor" from Kiwa. It uses a remote pre-amp and control box that employs variable band-pass tuning. If you want to build one in kit form, the INSPIRE project sells the VLF-3, probably your best bet, ($120). Just remember, you need to be a 1/4 to a mile away from power lines depending on how high the voltage is. Hope this helps. John

I also forgot to ask what size awg magnet or hookup wire would you recommend for a H or B-Field loop antenna. I know that anything like 30 awg which I used to use to build a box frame antenna that I currently am using with my 1 MHz crystal oscillator VLF converter connected to the KA-1103 or Grundig G5. I wish that my Radio Science Observing Volume 1 and 2 CD-ROM would worked with my Windows 10 32 bit HP laptop since there were various programs for constructing loop antennas. I just don't know how to get 16 Bit software to work. I greatly appreciate the help and support from this group, and glad post more often.

How many turns would you recommend for a well performing H-Field , B-Field loop antenna, and what size is best for VLF natural radio?

It's for my first floor apartment in the living room VLF natural radio receiver. Possibly will place the loop on the ground on the carpet.

As someone else already mentioned, the e-field active whip Natural Radio will be much more sensitive than any small loop Natural Radio. And one needs to get as far as possible from all sources of AC power. You won't hear anything but the very strong 60 cycle hum if you're hoping to listen inside your apartment! At least find a park or playground without any AC power within several hundred feet, you might be able to hear some stronger sferics around sunset or sunrise. Otherwise you'll still just pick up the very strong AC hum which will overpower any weak signals.

Good luck!

Steve AA7U (who used to do Natural Radio listening when I lived where I could drive to a spot several miles from a power line)

Topic: 11458 Message: 11468

Adam, Steve is correct. E-field receivers produce much stronger signals.You need a strong signal to have any chance of decent reception at home. Early on, I used my Kiwa with the pre-amp/whip high over head my house and using active high pass filtering to blunt the overpowering 60 cycle hum. Somewhat effective, heard some whistlers early in the morning. Then i discovered Wolfgang, DL4YHF who wrote software for a program called Spectrum Lab. Has a waterfall display for audio analysis, DSP for better filtering and logging capability. Easy to use and free! Check it out. Great for VLF work in general. John

11469. Re: Natural Radio simple e-field receivers

Adam:

Several easy-to-build Natural Radio receivers are listed at this site:

http://www.techlib.com/electronics/VLFwhistle.htm

They are all e-field receivers; the opamps are readily available and inexpensive on eBay, from US sellers.

Good luck!

Steve

Maxwell - that's bordering on genius level advice. Two magnetic loops, because any single loop will block most of the noise, given directional and null characteristics. But two, and a noise canceling circuit would lock you into canceling out the noise source regardless of the kind of noise.

Maybe an MFJ-1025 or MFJ-1026 for noise canceling, plus start with a MFJ-925B MLA. Likely I would get a single MLA first and see if a simple vertical antenna could work to tune out the noise, and then increase to dual magnetic loops, if I need even further correction.

getting kind of expensive at this level in costs, but am sure no worse than the typical $1000 many drop on antenna systems.

G'day Kevin, It gets better. I was listening to Queensland BCB station one night when the thought ocurred to me that the Phaser instructions suggested that you could cancel not only the noise but the signal of the target station as well.
I aimed both loops at the station, threw the appropriate switch and sat back to hear the "Sounds of Silence".
Instead I was presented with the audio of two weaker stations under the Queensland station, one with female announcer and the other a male.
I sat back gobsmacked. It was the end of a long day and did not try to identify the stations.
If we look at the reception qualitys of a loop the reception lines of the loops cross the target area and diverge on the other side, also the loops lines continue "behind'" us and diverge there.
The signals for the weaker stations must have been rideing on one of those lines on the same frequency and only became apparent once the stronger stations influence was extinguished.
Regards again Max vk2tti.

11472. Simple Varactor-Tuned Loop Antenna by N7ZWY

Yahoo group: loopantennas (2013 — 2017)

Hello,
I have built the Simple Varactor-Tuned Loop Antenna by N7ZWY but it does not work. I just have more noise when supplied with 1 to 4 volts.
I don't know where to look at, and I just have a SDR to test.
Any help would be really appreciated.

Which varactor(s) are you using?

I bought a bulk lot of 300 MVAM109s and found about 10 of them that
produced noise through high reverse current leakage.

Just a thought.

Hi Jim, I have two MVAM109. They look good with a DMM.
How to ensure they are not generating noise?

11475. Re: [loopantennas] Simple Varactor-Tuned Loop Antenna by N7ZWY

Defective varactors could be a serious problem. I have contemplated designing a similar loop using a dual 365pF variable capacitor, using the coupling technique that I used for the transmitting loop.

Many of the MVAM series varactors out there are from China and are of quwestionable quality. If you suspect them, you may want to use the 1SV149 varactor, which can be bought cheaply on evilBay:

www.ebay.com/itm/201056378032?_trksid=p2055119.m1438.l2649&ssPageName=STRK%3AMEBIDX%3AIT

From: Tim Hills
Topic: 11472 Message: 11476

If you don't have a 'scope or spectrum analyzer the easiest way is to attach a short wire to the Cathode of the Varactor and monitor it with a portable MW radio tuned to a "quiet" Freq. while you vary the Voltage. Or measure the Current under reverse Voltage. If it's more than a few uA then it's a bad varactor.

I see Chris mentioned the 1SV149 which I have also used for tuning loops, etc. Probably your best bet is to replace them if you can.

The MVAM 109s I got were likely Chinese made or factory "dropouts". Of the 300 between noise, funky V/C curves, narrow range, etc. the yield was about 120 usable. Considering what I paid for the lot I still got a heck of a deal. If you don't consider my time put into them...

Hi Chris,

I concur about the attainable Q of air-variables versus varicap varactor diodes.

However Teledyne Crystalonics still manufacture a range of decent varactors suitable for tuning HF loops. The IN5714, IN5717 family of high-capacitance varicaps (up to 500 to 1000 pF) sport a Q of circa 200 to 300 or so. Crystalonics produce a large range of legacy and JAN semiconductors that have elsewhere long attained *unobtainium* status. They specialize in supporting the availability of parts for the defence/mil market which has very long lifecycles.

Their unique product line includes a very capable low-noise high dynamic range JFET, the CP-650 and a few other variants thereof. This family of unique JFET devices sport extraordinary transconductance / gm circa 0.15S to 0.25S / 150,000 to 250,000 micro-mhos and low noise figure with high drain current capability enabling amplifiers with exceptional dynamic range and intercept points, particularly when deployed in push-pull. They make excellent wideband antenna preamps with NF circa 2 dB in Norton style topologies.

These unique CP6XX devices are actually FET arrays comprising a multitude of 15 parallel devices in an integrated die single package.

Indeed. I keep looking for specifications for MEMS variable capacitors and
I can't find any - they seem like expensive vaporware right now. They
might be usable for transmit at QRPp levels.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)
> - - - discontinued

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11484. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-06-01 13:19:47 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11484

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11485. Ferrite Rod antenna shild

11486. MFJ-9232

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-06-27 01:24:47 UTC
From: Raoul Meunier
Topic: 11486 Message: 11486

Greetings!

I purchased a MFJ-9232 a couple weeks ago and I tried it today.

I made a loop for 24 MHz as described in the manual, and tried it using 5 watts, to be conservative. It tuned fine, a little “touchy” and I was able to go down to 1.3:1 SWR. Same on 28, and 21 MHz. Great!

My problem started when I increased the power… At 10 watts, it arced, showing a sudden increase in SWR.

After that, the “Tuning” capacitor no longer turns 180° but only about 45°… I opened the unit and found the capacitor still warm, and the dielectric material that separates the plates was stuck to the rotor.

May I ask you what would the best way to contact MFJ be to ask them about the warranty this thing is supposed to have… I have no experience in this field.

Your comments will be very much appreciated!

I bought this unit having in mind I could use it in the 15-20 Watt range… No luck.

73 de Raoul, CE3RY

Raoul,

See the following URL : http://www.mfjenterprises.com/warranty.php for
MFJ Warranty Coverage.

As long as you didn't apply more than 25 watts to your MFJ -9232 mini
loop tuner, MFJ should be willing to repair it- under their 12 month
warranty.

73, Jim (N6MV)

11489. Wellbrook FLG100 and ALA100 modules for sale, also Quantum V3 Loops

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-01 03:34:36 UTC
From: daiche@...
Topic: 11489 Message: 11489

I have been upgrading to the newer 'LN' product and have 4 Wellbrook FLG100 modules and 2 Wellbrook ALA100 modules for sale at good prices. These don't come with the interface/voltage injector adapter and they are used, but in good shape. You can get Russian made voltage injectors for $18 each. I want $125 each for the Wellbrook modules, CONUS only. If you are interested, contact me at my email:
'daiche -at- yahoo -dot- com'. I can take PayPal payments and am ham operator N7NZH.

Since I have moved on to mostly SDR radio listening, I also have 2 Radio Plus Quantum V3 loops for sale and will include an extra 15" ferrite head with each. They come with 7.5" ferrite heads with variable gain. The larger 15" heads have no external antenna adaptors. I want $175 each for the Quantum loops with 2nd ferrite heads.

I will pay shipping on CONUS orders and would consider a further discount for multiple items. Thanks!

Dave Aichelman N7NZH Grants Pass, Oregon

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11491. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-01 13:32:00 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11491

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

Topic: 11489 Message: 11492

OK Guys,

The 2 ALA100's are gone but I still have 4 FLG100 modules and 2 Quantum V3 loops for sale with a 2nd 15" ferrite loop head included with the Quantum's. I'll offer a lower prices for the purchase of multiple items.

For those of you who don't know the FLG100's, they are typically used with a fixed or variable resistor on the other end of the loop to form a null in that direction, in other words, a unidirectional pattern. They can be used as bidirectional antennas as well, by leaving out the resistor, with a little loss of sensitivity. I have used Wellbrook products from Andy for many years and they are all good. I have been upgrading to the newer LN version of his products and have these modules available.

From: Richard (Rick) Karlquist
Topic: 11494 Message: 11495

You would be better off adapting a dipole to your apartment.
Bend the wires if necessary. Put a loading coil at the
feedpoint. Tap down on the loading coil to get an
impedance match. A moxon type dipole might make sense
with the ends vertically along a corner. You should be
able to get at least a total of 1/4 wavelength, maybe
3/8 wavelength this way.

Thanks for your comment, KT (what's your name and call sign?).
The good news for me is that MFJ will send me a couple capacitors; they mentioned a possible faulty cap in the unit I bought. I will not lose the warranty even if I perform the change.
It's a very simple unit...
Anyway, even though my expectation was to use it with up to 25 watts, I will try it at 5 Watts... It's dissapointing but I knew I was running a risk when buying from MFJ.

Thanks again and 73,

11498. Upgrading ALA1530LN to ALA1530LNP

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-09 22:35:18 UTC
From: yoonh.choi@...
Topic: 11498 Message: 11498

According to the email reply I got from Wellbrook, the only difference between ALA1530LN and ALA1530LNP is the antenna interface that has 9dB gain. So I purchased the 9dB interface separately, to upgrade my ALA1530LN to the "Pro" version. I upgraded it for more gain on 7-15MHz because I found the ALA1530LN weaker for those bands. Now all bands got 9dB boost so MW or low HF is even stronger than before, but with higher noise floor as I'm using the loop indoor so the local noises are also boosted. The upgrade works for me anyways, and I can switch back to the passive interface to downgrade if needed.

Thanks! I enjoyed the tests described in that article. I have all those factory made loops.

The PK tuned Loops from Australia are mostly larger and area matters. Available amplified and unamplified, and for LW and SW as well as MW.

Like the author I find the CCrane amplified ferrite takes time to tune in just right, and is not significantly better.

It is hard to find big differences among tuned loops similar in size. They DO help all but the very best portable radios.

I have some Litz wire loops and they tune much more sharply, needing a gear reduction drive or some other way to tune very slowly.

Thanks again, a very interesting article. - FARMERIK

11518. Re: New file uploaded to loopantennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-25 18:07:50 UTC
From: Mark Cromwell
Topic: 238 Message: 11518

Thank you for the feedback. The main reason for posting this was that I had never seen any measurements comparing these passive loops. Just subjective impressions. I suspect there would be some minor variations if I did them again (since they all involve "tweaking"), but since the signal strength tracked the loop areas, I'm thinking what I have is useful for comparison. This also opens the possibility of others doing cheap and dirty measurements the same way if they have receivers that give some good objective readings.

I'm mostly just a lurker on this group and others, but I wanted to say that I appreciate the informational contributions I've been reading and the quality of the discussions.

Hi Mark,
Thanks for your great contribution to the group.
One very important parameter of loop antennas is the null depth.
Did you have a chance to measure it?

73, Mike

11520. Re: New file uploaded to loopantennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-27 21:52:58 UTC
From: mcromwel@...
Topic: 238 Message: 11520

I did not, Mike, but I may go back and try to add that info. The fact is, it didn't occur to me because the density of available signals is pretty low up here in the boondocks during the daytime. In order to do a good job of that, I'll need to determine more precisely the broadcast direction, so it may be a few days before I get to this. Or I might just pick a couple of stations and do it quick and dirty. Good suggestion. Watch for a rev 2 of the article.

11521. Re: New file uploaded to loopantennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-29 12:12:38 UTC
From: farmerik@...
Topic: 238 Message: 11521

I really appreciate all the work you shared already.

Possibly if your radio has ETM, you can point the loop antenna in different directions midday and do station counts. You would still need to tune in each frequency though.

The GP-5/SSB radio is not expensive and has a DSP chip. It tunes the loop itself at each frequency so it is a nice test bed. The 1/8th inch antenna jack connects on all bands, LW MW as well as SW. So it will retune the radio to the external loop at every step while ETM scanning the MW band in seconds. With that maybe just run a test every 30 degrees or so of 180 since the patterns will be bi-directional.

Online some where I have seen a 'calculator' to give signal strengths for any location with bearings I think. Figuring that out is complicated not only by station power but by directional patterns and signal path conditions. Better to just test from your location is my opinion.

-FARMERIK

11522. Re: New file uploaded to loopantennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-07-31 01:03:32 UTC
From: Mark Cromwell
Topic: 238 Message: 11522

Thanks for the suggestions. Being unemployed in this "booming" economy has imposed some restrictions on my ability to obtain ANY new equipment, however inexpensive.

I did actually rerun the tests for a couple of the frequencies. Because I am limited to inductive coupling to the radio I used, the results revealed a melding of the internal ferrite bar antenna with the air loop nulls. I ran the test with just the internal radio antenna (as a control) and then with each of the antennas for two of the station frequencies. As it turned out, I didn't need to know the station directions. I just put the radio and the loops onto a turntable, tuned to the frequency and rotated the entire setup until I got maximum and minimum readings.

I will probably republish the article with the results, but the bottom line is that it's difficult to separate the external loop null depth information from the data. Watch for more.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11524. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-08-01 11:06:01 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11524

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11528. Broadband loop antenna amplifier

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-08-08 15:25:54 UTC
From: makidoja@...
Topic: 11528 Message: 11528

Hi all

I want to build a broadband rx loop antenna to cover 15m to 80m, my thoughts are to have 2 loops about 20m in dia 90deg apart, feed these to a relay so the direction can be changed simply.

So what I'm looking for is a low noise preamp with enough gain to shove the signal about 300m along WF100 sat coax.

Does anyone have such a design please?

I have contacted Welbrook but there only solution was 2 x ALA100LN and remote power source, this makes it an expensive trial.

Thanks in advance for any ideas, designs or guidance

Jim M0CKE

Hi Jim,

I sat back for a while, in case there was someone with encouraging ideas for you. However, it seems there are none, so here goes with some thoughts:-

20m diameter for an amplified HF loop looks like a recipe for overload and intermod. Amplified loops are generally a fraction of a wavelength - are you sure this is the right solution?

A 300m feed is going to give you problems to solve. On top of the signal loss down the cable, there is the supply voltage loss going up the cable to your amp. No wonder Wellbrook suggested a remote power supply.

Sat coax isn't wonderful. Have you looked at the losses for that sort of length at 20 Meg? There is also a considerable potential for Common Mode interference. Better shielding would help, but you will probably find quite a few problems to solve.

Have you looked at Chavdar's amp? [LZ1AQ - he posts on this list]. He uses Cat5 cable, which has losses at the lengths and frequencies you seek too. But his documentation tells you how to make allowances for the supply volts loss. And his amp is cheaper than two ALA100's.
Consider putting the receiver at the antenna, and using a LAN to get the signal back to the shack.
Or, you could use something closer to home ;)

Sorry not to come up with the Magic Bullet.

Let us know what you try, and how you get on.

Best Wishes
David, GM8XBZ

Attachments: 1 described; binary payloads are missing from this source WARC

The 20m diameter loop is very large, and will have resonances in the HF range. What is the point of such an oversize loop? I would suggest that if you have the space you qualify for short Beverages, running a wire from bamboo canes as a test would be cheap to do. Far end termination is not vital but very simple to do. A simple ring transformer is needed to bring down the impedance to receiver level.

For HF use most active loops use a small diameter loop run into a current amplifier to get a flat frequency response, the output of a small loop increases with frequency but so does the inductance so the combination is non-selective. However when the distance around the loop approaches quarter wave the simple model breaks down. A 1m diameter loop is 3.14m around so that at 28MHz it has departed from the simple model and needs other means to equalise. So a 20m diameter loop with over 60m of wire would not make Top Band as an untuned broadband loop.

The limit on sensitivity is set by the external noise floor, as you enlarge an antenna you reach a point where there is no improvement in signal to noise just more of both. At low frequencies natural noise levels are very high so a loop a few m across is noise limited. There is little point in going above 2-3m at low HF while 1m is big for 30MHz.

Feeder loss is significant with small diameter cables at 300m long, a small diameter cable will loose around 20dB at 30MHz, a large diameter cable will be very expensive for a 3 reel run. Twin feeder works very well but needs supporting off the ground. Cat cable is available in one continuous length of 1000’ but will loose signal too.

I would suggest that you try a smaller loop at 100m from housing QRM, you might not find much difference to 50m in terms of noise levels, but it is much more practical.

Jim,

Another disadvantage of a 20m diameter loop compared to a small loop is absence of the deep null.
Small loops can be rotated to minimize their coupling to the electrical grid noise, thus maximize signal to noise ratio. 20m loop can not. I would expect it to be no better than a 20m wire in terms of signal to noise.

A preamp for small loop has totally different design goals compared to preamp for bigger loops and wires, as others already pointed out. Bigger loop preamp doesn't need the ultra low input impedance, but does need more strong signal handling capacity.

11532. For Sale is a 10" X 10", Tri-Coil, Dual Band, Ferrite Sleeve Loop Antenna (FSL)

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-08-21 19:28:58 UTC
From: everettsharp@...
Topic: 11532 Message: 11532
Attachments: 4 described; binary payloads are missing from this source WARC

I have for sale a 10" X 10" Tri-Coil, Dual Band, FSL. It is made using 86, 5 mm X 16 mm X 125 mm Russian ferrite bars, that are epoxied to the substrate. The ferrite is covered with 1/2" Polyethylene foam and has 3 coils, that are contra wound, using Double Layer 660/46 Litz wire.

The MW band coverage is 1700-635 KHz (with 3 coils in parallel). LW band coverage is 700-155 KHz (with 3 coils in series).The tuning capacitor is a high quality 2 gang 365 pF variable capacitor with a 8:1 tuning ratio and the band switch is a 4 PDT. The Lazy Susan is all aluminum. I have added a 50 ohm output so a desktop radio can be connected to the loop, by using a one turn coupling loop and a matching transformer so that when a radio is connected to it via the 50 ohm connection it does not destroy the loop Q. You can also induction couple to the loop by placing a portable radio near the loop. It can turn a very small portable radio in to a high performance radio.

I have built several FSL's and have sold them all, this is by far, the nicest and best performing one that I have built to date. It looks like a fine piece of furniture. I am asking $775. There will be an additional shipping cost, in addition to the asking price. If anyone is interested please contact me off list at everettsharp@....

Hi ?.

A simple 'net search turned this up at Universal Radio (and many others):

http://www.universal-radio.com/catalog/commrxvr/al4a.html

Not much to it. A single turn of wire, a 1/4in fone plug and some
spreader arms and mast. Dimensions are in the write up.

I had thought of buying one but only for esthetics for the SPR-4 but
most sellers want ~$200 or more.....

I had one in the eighties with my SPR-4 - it seems to me it was a single turn, but of RG-174. The shield would have been broken somewhere, ideally at the top, so that it would act as a Faraday shield, albeit an unbalanced loop. I also seem to recall that the loop preamp, part of every SPR-4 and SW-4, was a common-base BJT - a low-Z input. I DF-ed my powerline EMI by running the radio off a marine battery in the back of my pu truck as my wife drove me around my subdivision. The noise peaked at the pole in front of my house, as I had determined earlier by walking with an $8 AM pocket portable.

We had more LW NDB's then - the AL-4 would display a local MW null of ~3 S units, same as <50 mile distant NDB's. It connected via a 1/4" phone plug, which put a lot on of torque an strain on it as an 'axle'. The loop was frequently noisey - and even intermittent as you rotated it. My homebrew jFET/feritte rod loop, similar to Gerry Thomas' Radio+ current version, which I now have - great product - presented a lot better signal to my new NRD-525 then, so I sold the SPR-4/AL-4 combo most of three decadeJs ago. Nostalgia is tough - I still look at SPR-4 auctions!

I'd think one of Gerry's loops would be more useful, although at $200 + the extra cost $100 LW loop, it would cost more than the average $200 AL-4.

Hi All

Sorry the 20m was based on the Welbrook loop, i think it's 20m overall wire length

I already have the LZ1AQ system here which works well but the antenna is for a different location.

I have also now looked at the cross country wirelss loop antenna HF Active Loop Antenna - Cross Country Wireless http://www.crosscountrywireless.net/active_loop_antenna.htm

http://www.crosscountrywireless.net/active_loop_antenna.htm

HF Active Loop Antenna - Cross Country Wireless
http://www.crosscountrywireless.net/active_loop_antenna.htm HF Active Loop Antenna Cross Country Wireless have released a HF Active Loop Antenna with a frequency range of 200 kHz to 70 MHz with extended coverag...

View on www.crosscountrywir... http://www.crosscountrywireless.net/active_loop_antenna.htm
Preview by Yahoo

and have spoken to the manufacturer about using Coax instead of the CAT cable which he is looking to possibly design.

LZ1AQ has also sent me details on how to take the signal via coax but leaving the control and voltage on the CAT, with increased voltage for losses.

I have no room for beverages, and I need the loop as far away from my transmitting antennas as possible, I have no option for a remote receiver, the loop null will be towards the transmitting antennas, which will be north from the RX loop, so the loop should work E/W

I currently have a multiband vertical 250m to the south with no preamp which works OK on 40 - 10 but I have nothing for the LF bands.

I was looking for a amplifier design for a Loop antenna which would give a flat response, I enjoy building my antennas.

So with the Cross Country in mind, what would design of preamp would work with this kind of loop dia?

Coax I'm using has a loss of 3.6db over 100m @ 50mhz and will be shield grounded at the base of the antenna and before entering the shack.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11541. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-09-01 13:17:44 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11541

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11542. Re: [loopantennas] For Sale is a 10" X 10", Tri-Coil, Dual Band, Ferrite Sleeve Loop Antenna (FSL)

> I have for sale a 10" X 10" Tri-Coil, Dual Band, FSL. It is made using 86, 5 mm X 16 mm X 125 mm Russian ferrite bars, that are epoxied to the substrate. The ferrite is covered with 1/2" Polyethylene foam and has 3 coils, that are contra wound, using Double Layer 660/46 Litz wire.
>
> The MW band coverage is 1700-635 KHz (with 3 coils in parallel). LW band coverage is 700-155 KHz (with 3 coils in series).The tuning capacitor is a high quality 2 gang 365 pF variable capacitor with a 8:1 tuning ratio and the band switch is a 4 PDT. The Lazy Susan is all aluminum. I have added a 50 ohm output so a desktop radio can be connected to the loop, by using a one turn coupling loop and a matching transformer so that when a radio is connected to it via the 50 ohm connection it does not destroy the loop Q. You can also induction couple to the loop by placing a portable radio near the loop. It can turn a very small portable radio in to a high performance radio.
>
> I have built several FSL's and have sold them all, this is by far, the nicest and best performing one that I have built to date. It looks like a fine piece of furniture. I am asking $775. There will be an additional shipping cost, in addition to the asking price. If anyone is interested please contact me off list at everettsharp@....

Hi Paul, David Balcaen VE2GYA here.

I am contemplating something similar, and wonder if you ever got a response?

My approach is to feed the 80m loop in the centre of one of the long sides, then "double up" the wire, all the way around then back again, to make the loop. 3 inch spacing between the runs. My thinking is the highest current will be at the feed point, then the zig, zag wires will be on the other three sides only, and provide proper matching for 80m.

I have a first version up, but it resonates at 4.2 mhz, so not all that useful. It tuned up okay on 80m with SGC230 at the feedpoint, with good reception reports, but I want to make it resonant. I am new to this group, so will try to upload an image of my planned antenna, in case anyone cares to comment before I put the day of work into getting it up on the roof.

73,

de VE2GYA

David Balcaen

11544. SWL Receive Array

Hi
Does any one have experience with and/access to Antenna Modeling/Design software?

I am researching the use of Loop Antenna(s) for receive only BCB/Shortwave in several arrays.

Also looking for information, ideas, designs of remotely tuning Loop)s).

The plan is for Antenna(s) to be mounted in an attic and and combing them to get something resembling 360 degrees reception.

For a/the first antenna I am looking at mounting a circular all in the same plane, on the surface of a light weight, hollow core, plywood, interior door, allowing a diameter of 28" on a 30" door.

Initially I am looking into two separate Antennas/Designs. One 550 Kilocycles, up to as far into the HF band(s) as is electrically and mechanically feasible; and the second in the other direction say 21 Megacycles down.

Then placing the doors at right angles to each combining their output to the receiver. Initially with a 4 to 1 Combiner Board made by a Ham in Malaysia that builds amplified four receivers to one Antenna Boards, and has built me a passive 3db loss, Combiner board using the same printed circuit board as his amplified board.

After the above I want to try connecting the antennas at their Base and sharing one Coax down lead to the radio.

After the above it gets even more wild. I want to look at four antennas in/on the surfaces a square box with an X insert. Here the plan would be to try four identical Loops sharing one variable capacitor and down lead.

Keep in mind that I am not interested in Nulls but sort of a ersatz, remote tuning, wide(ish) band omni- directional, 360 degree antenna.

OK. Now that you have stopped laguhing or crying, give me some constructive criticism.

Please take two minutes of your time to send a letter to your two Senators in support of HR 1301 which unanimously passed in the House of Representatives.

The passage of this bill will enable all of us to have a magnetic loop antenna at our residence, even though we now have CC&R's.

Simply click on the URL below and fill in your zipcode, name, address, and e-mail address.

That's all it takes, for the letter is already composed - and it will be addressed to your Senators, courtesy of the ARRL.

Many thanks in advance, for your help and support.

All the Best,

73, Jim (N6MV)

Date: September 22, 2016
Subject: HR 1301 - Amateur Radio Parity Act - Senate Letters

We have an opportunity to positively affect Amateur Radio for years to come. H.R. 1301, the Amateur Radio Parity Act, has unanimously passed the House of Representatives and moved on to the Senate for consideration. All you need to do is spend two minutes of your time to send an email to your two Senators supporting the Bill. By doing so, you will have helped the future of Amateur Radio by guaranteeing our ability to have an effective outdoor antenna in a deed-restricted community.

The number of people living in such communities grows exponentially each year. Often, a ham homeowner has no choice but to live in a community restricted by covenants. There are nearly 3/4 of a million licensed hams in the United States, more than ever before. But that may change if we are forced to live in a community that refuses to allow an antenna.

Help yourself and help your fellow hams. Go to this link:

https://arrl.rallycongress.net/ctas/urge-senate-to-support-amateur-radio-parity-act

Enter your zip code and follow the prompts. The letters are there.
All you need to do is fill in the blanks, hit save, then send.

That’s it. Under 2 minutes and you’re done.

If you haven’t yet done so, please do so today. Your voice counts!

Hi, Jordan. I use a free antenna modeling program called MMANA which works quite well. I've built a number of antennas using it and they work as predicted. Included is a large library of designs which will help you learn to use the program and understand it's features.

The website is: MMANA-GAL - MM HamSoft http://hamsoft.ca/pages/mmana-gal.php

From: jjdobrikin@...
Topic: 11549 Message: 11549

Hi

I am in the final phase of designing and building an Indoor SWL Receive Only Loop Antenna.

I plan on a loop diameter of twenty- eight inches 28" maximum practical size for an interior hollow core door.

My first question is what Loop Wire should I use, Litz, Stranded (speaker/zip cord), Solid (what gauge?),
Coax (what Type?).

For an alternate design, I am looking at foam Insulation/builders board again in 28" to 30" diameter with a Satellite Dish Rotor to mount on a protected outdoor balcony on the 8th floor and top,19th floor of a concrete & steel Apartment Building.

The Satellite Rotor is somewhat unigue. In that allows positioning and RF on a single Coax cable as well as azimuth and elevation positioning

Answers, comments and or constructive criticism requested.

From: Andy
Topic: 11549 Message: 11550

For a receive-only shortwave loop, I think any wire would be OK. So pick one that is inexpensive and easy to work with. Whether that's solid or stranded, it's up to you. I think a small gauge (larger AWG number) is probably OK, because antenna "gain" is not very important for receiving purposes on shortwave frequencies. HF reception is usually dominated by received noise, e.g. cosmic noise, not by the noise in the receiver, and the level of noise ultimately determines how quiet the signal is that you can just listen to.

I think Litz wire is probably overkill for a shortware receive-only antenna wire, for the same reasons.

Coax too. (Although, there are so-called "shielded loop" antennas using coax, which are supposed to reduce reception of man-made noise. But the shielding doesn't actually shield the antenna from receiving anything undesirable; what the shield does, is help make the loop electrically balanced, which is good.)

Antennas like this are often hotly debated, so I'm sure there are people who dispute what I wrote.

Andy

From: John
Topic: 11549 Message: 11551

It depends on what type of loop antenna, tuned or untuned.

If a tuned antenna, Litz wire doesn't have much effect above about 3 MHz. 18 gauge or large diameter (smaller number, 14, 12, etc) is preferred, or occasionally the outer conductor of coax cable.

For an untuned loop used with a very low impedance amplifier, large diameter is preferred, coax shield or copper pipe.

Smaller wire will work, and the test is always does the antenna pick up more signal than the noise generated inside the receiver. If, when the antenna is connected to the receiver, the background noise changes from a very smooth hiss, to a more uneven, stronger, noise, then the antenna is working, and a more perfect wire won't make much difference.

Your Mileage May Vary.

Mose of the long wire antennas I've put up in the last 60+ years have been about 24 ga wire.

John

Agree with Andy and John, wire type is not that important for the loop (except the untuned loop loaded to a low input impedance amplifier).
Remember that the main advantage of the loop is not gathering more signal, but the ability to null the single strongest noise source, thus providing the best Signal to Noise ratio. This is why the better balanced shielded loop is used, as Andy mentioned. It has a deeper null if loaded properly.

An interesting site:
http://www.lz1aq.signacor.com/docs/fa-eng/Weak_signals-mag_loop_engl.htm

On My opinion the copper tubing or multilayer Aluminum is the best option. I built up several resonating loops with wire, but tubing has higher Q and bandwidth. I had good results with varactors also, especially BB112. With a cathode to cathode mounting (no condensers) and 32" (81 cm) copper tubing of 12mm I cover from 6 to 30 mhz.

100% ORIGINAL MOTECK V-BOX II SATELLITE POSITIONER

GUARANTEED TO BE ORIGINAL
THIS IS AN ORIGINAL MOTECK, THIS IS NOT A CLONE PRODUCT LIKE MOST POSITIONERS SOLD TODAY vbox II is the last version manufactured by Moteck, all later versions are Clone and not manufactured by Moteck

OPTIONAL REMOTE CONTROL IS INCLUDED

The Moteck V-Box II allows allows a DiSEqC 1.2 satellite receiver to control a conventional actuator style 36 volt motor. It takes DiSEqC 1.2 commands from your MPEG-2 / MPEG-4 DVB satellite receiver and converts it into 36v pulse and sensor to store positions, 60 positions can be stored. It can work as a stand alone positioner too. FEATURE:
Compatible with DiSEqC 1.0 /1.2 RECEIVER or Any Receiver
Compatible with any Reed Switch Actuator or H-H Mount
re-synchronize Function
3 Digit LED Display
Drive Dish up to 3M
99 Satellite Positions
60 Programmable Memories
Fine-tune EAST / WEST Buttons
Optional Remote Control INCLUDED
Overload Protection (Auto-recovery)
Anti-Noise Design
Remote Control Included
NOTE that the power specs are for North American Standards.

V-BOX II Input: 110 VAC / 60 Hz Output: 36 VDC Max. Dish Diameter: 3M / 5M Max. Output Current: 2.5A~ / 4.2A~ Max. Power Consumption: 80W / 100W Protocol: DiSEqC 1.0 / 1.2 Positions Memories: 60 Controlled by: DiSEqC 1.2 / 1.0 Receiver or Optional Remote Control Display: 3 Digits LED Resynchronize Function: YES Manual Buttons: Power ON / OFF, EAST / WEST Protection: Software Limit Protection Electric Overload Protection

THIS IS AN ORIGINAL MOTECK POSITIONER
THIS IS NOT A CHEAP AFTER MARKET

100% GUARANTEED

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11559. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-10-01 12:54:36 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11559

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11560. Shielded loop question

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-10-03 18:15:06 UTC
From: dannibou@...
Topic: 11560 Message: 11560

Hi. I read some articles on the shielded loop and the majority use a single wire round coupled with a preamp. One article said that this antenna covered the SW band and another article proposed a identical loop of the same size but which covered the AM band. Should I assume that a single turn can cover multiple frequencies? Where is the difference? In the preamp? Thanks for Any explanation.
Danny

Hello Danny

Check this website out and see if you can learn some loop-tricks ===>

*http://www.66pacific.com/calculators/small_tx_loop_calc.aspx
<http://www.66pacific.com/calculators/small_tx_loop_calc.aspx>*

Mess around with wire diameters and see what it "costs" you.

I fabricated a TX/RX-loop using 10-feet of 3/8th-inch copper tubing and
a coupling loop. It is tuned to 10.138700MHz and I am running 5-watts
into it.

GREAT reports from all over the USA, JA, KH6.VK and ZL. So far no EU
copy or decodes.

73 Dick/w7wkr and wd2xsh-26 at CN98pi and NPOTA unit RC12

From: gnuarm.2007@...
Topic: 11560 Message: 11563

A loop antenna of any practical size for any but the highest frequencies is "small" compared to the wavelength. So the size of the loop is not so important to it's operation for receive having only an impact on the signal strength across all frequencies (larger gives a stronger signal, but also more noise so not improving the received SNR). The loop is a fixed inductor and is tuned by adjusting the capacitance added.

It is possible to use a loop without tuning in which case the size of the loop still has little impact unless you are near self resonance which is largely determined by the loop construction.

Regards,

Rick C.

Thank Rick. That explain why a loop can be effective for different band. Anyway, I prefer tuned loop but for a shielded one. it's hard to find a site with a diagram and construction plans. Money, electronic and mechanical issue are not a problem. Just need a good "how to" site.
Danny

Hi
I have also been reading and researching thru the Internet for good HF SWL Receive only antenna including Loops remotely tuned.

Would you be able to give us link(s) of the article(s) with the conflicting information?

From my research and reading I have come with the following guidelines.

A single Long turn, Low Inductance, over the widest Area possible, establishes the highest usable frequency.

I am looking at 4 by 8 foot Foam board with a circle of 39" diameter, and/or a square 39" per side, as well as a larger rectangle 39" by 48"/50" to get a longer wire Length and larger Area.

The lowest usable frequency is a function of the distributed capacitance and maximum of the variable tuning capacitor.

Longer wire Length, more Turns, gives a lower usable frequency but it lowers the highest usable frequency.

Loop conductor is a function of your mechanical construction skills and ones search of the Holy Grail of low inductance and maximum surface area of the conductor(s).

Pipe Copper or Aluminum
Thin metal bar stock 2' to 3" wide 1/16' or less
Wire: multi strand speaker/zip cord, Litz Wire, Flexweave, Ribbon Cable (wired in parallel), sold core wire.

If one goes for Passive the the Pickup Loop is a toss. Very little in the literature comparing the different designs and wire type(s)

Long lead ins call for low noise pick up Coaxial Cable.

Active Amplifiers are wide band and do not effect the highest usable frequency which is determined by the physical parameters of the loop. Most have mechanisms to add capacitance to define the lowest usable Frequency.

Since you asked, here is a construction article:

http://www.n6rk.com/loopantennas/NCJ_loop_antenna_N6RK.pdf

As shown, the loop covers about a 3:1 frequency range,
about 1.6 to 5.5 MHz. If you add additional tuning diodes
you can get it to cover the AM broadcast band. It will
have less sensitivity there because it is smaller in
terms of wavelength, but that's OK because the signals
in the broadcast band are much stronger than SW.
If the loop is reduced to a circumference of 10 feet,
and only one tuning diode is used, it can cover up
to 10 MHz or so.

I have unloaded PC boards available.

Untuned loop antennas are broadband. the Wellbrook Communications ALA1530 antenna, for example, has a frequency range of 40 kHz to 30 MHz.

The amplifiers which are part of the loop antennas sometimes restrict the frequency range. An antenna designed only for HF, for example, might have filters to attenuate the MW broadcast band to prevent the higher power signals there from overloading the ante,na or connected receiver.

There are several good homebrew untuned loop antenna designs floating around on the internet.

Tuned loop antennas are a different subject. The frequency response of those depends on the minimum and maximum values of capacitance that are available to tune the antenna to resonance. These are best used for transmitters only for shortwave because of the inconvenience of retuning the antenna for each frequency change, but are common for medium wave only receiving.

Hi John,

look in the files; MONTAGE INSTRUKTIE LOOP VERSTERKER S-120-B DOC.doc
It is in Dutch bud you will understand the schematic.
I use this stable amplifier for years now from aprox 150 KHz up to 144 MHz with a +20 dB gain amplifier.
Did make also APT sat pictures with this antenna and my KTH-SDR receiver.
It is a wide band antenna for LW, MW,SW up to VHF, Do you need more frequency ?

On the RF output you can connect band filters and or attenuators if you receiver not strong and become overloaded.
It is not a kit anymore bud I have the PCB layout in GIF format.
Shall put the photos in the photo map.

Hi Danny,
An shorted loop is a closed winding and not tuned because it is a shorted winding.
The electric field is therefore shorted as well and only a magnetic field will introduce a current in the loop. Many magnetic frequency components induct a current.
A small part of the inductance is in this closed loop circuit the input winding of the input balance transformer.
Of coarse there is a difference if an aluminum strip is used with a low self inductance and low skin los.
A thin wire as a loop has a greater loss and more self induction bud the amplifier amplify all incoming signals and compensate the loss.
The sensitivity lobs shell be different depending on frequency, loop parasitic capacity and amplifier load.
Anyhow this closed loop works well in a broad spectrum and I used this principle also for world radio design with the Silicon Land AM/FM shortwave Si4835 receiver chip successfully.
With a loop diameter of 70 cm many middle east stations and fro china has been received.
Those station are strong of course.

I have two home-brew construction articles for receiving antennas in the files section:

ElectricallySmallResonantLoopForMediumWave.pdf
<https://xa.yimg.com/df/loopantennas/ElectricallySmallResonantLoopForMediumWave.pdf?token=S4FM5Atirhj611Gkqonif8co2-2I0gmq9F7j9hbZdoNb8vtMqttlsgoSWgMAuE7xU_hpOKT6y9i6PrA7M_cEYMj6FnwXHGCW84h9CjNrSWnIgu1XevoxAhnPJhbUP0texu9Zb7__WDsOXE5lWA&type=download>

and
Electrically Small Resonant Loop for Shortwave (Oct '14).pdf
<https://xa.yimg.com/df/loopantennas/Electrically+Small+Resonant+Loop+for+Shortwave+%28Oct+%2714%29.pdf?token=WDNvkEZTNH4_FHLWt1g66LNzklGFcXfJH0dDMdMA_CnPM2YfldDsePowA_2p077hgMMYxJckW6w2kRHOtV_WBm2sG6kE38ApRreyT54n4u8D_x_BB82QgjPSM2lom7Noc_ORyKt9c_bd1odUtLVclhVuXGQNMwGXmeOoKkUlSYybZJvYIFX88f9yA6lsBx0&type=download>

These are based on basic loop antenna theory contained in numerous engineering articles published in the early days of radio, many of them from the Proceedings of the IRE/IEEE. They are passive, resonant loops, transformer coupled to a low-impedance pick-up coils, which feed the receiver through twisted pairs.

Transformer coupling allows the primary circuit to "freewheel" in space under a minimum load, which results in a very high Q (i.e., narrow band response).

The pick-up coil on the medium wave antenna, is in fact shielded. It is also possible to produce ideal nulls by balancing the primary coil. My experience is that shielding should only be used for low-impedance, non-resonant coils, as the capacitance from the shield greatly limits the inductance of a resonant coil.

Why? For electrically small loops, the "effective height" is directly proportional to the NA product, where N is the number of turns and A the area of each turn. Thus, it pays to maximize the inductance:capacitance ratio for a resonant antenna.

The pick-up coil should produce an output impedance roughly matching the input impedance of the receiver. For antennas having a limited tuning range, it will be possible to do this with a single coil. However, for those designed for large SW tuning ranges, it will be necessary to adjust the size of the pickup coil with a tapped switch or perhaps using a series-fed, low-impedance tuned circuit.

I am fortunate to have a shack in a second-floor room in a frame house. The antennas perform quite well beside the radio, and I have never had to contend with remote tuning.

Regards,

Bob C.

I'm about embark on my first attempt at winding a ferrite bar antenna (for a WWVB receiver). I understand the theory, and how it's all supposed to work, but that's where this antenna and I stop right now.

Does anyone have any practical tips that they feel will make my life easier?

Again, I don't need an explanation of how such an antenna is supposed to work in theory; I understand that reasonably well. I'm looking for war stories.

Hi

WWV is HF what frequency(s) are you Planning?

Litz wire and probably a long strong ferrite.

You might want to look into a Q Multiplier Loop to get the HF range(s)

WWVB is on 60 kHz and so is in the LF band, not HF.

There are a variety of potential antennas I found for this frequency range. A ferrite loopstick is just one type although very common because of its small size. While I have been looking at building a WWVB receiver myself, my requirements for the antenna don't allow the use of the ferrite loopstick. I need an antenna that gives as large an output signal as possible.

Do you know how strong the WWVB signal is in your area? Do you have any idea of the background noise level?

Are you building a conventional WWVB receiver using one of the many receiver front end chips and an MCU? If so, which receiver?

Regards,

Rick C.

To amplify a little: It occurred to me that 60 kHz is will within the capability of almost any microcontroller to directly digitize.

I'm therefore playing around with hooking a minimal antenna and front end onto a suitable chip, and doing all the requisite signal processing as DSP on the chip.

Since the consumer devices I mentioned all use loopstick antennas, it seems like a reasonable starting point. I can, of course, fall back to a larger open-air loop if it proves necessary, but I want to try the bar antenna first.

Dunno how much will come of it, but it should be
fun trying.

Agreed. It's also where I want to start, because if I can make it work, it's a nice compact unit. Basically, the same reason anyone would want to use a loopstick.

I'm in a crappy area for receiving it; east coast near Annapolis. I'm fully aware that there's a very good chance I won't be able to get enough signal out of a loopstick. I want to try, though. If it doesn't work, I'll go to a (much) larger air loop.

> Are you building a conventional WWVB receiver using one of the many
> receiver front end chips and an MCU? If so, which receiver?
>

It's an experiment in seeing what I can get a microcontroller and minimal front end to do. 60 kHz is well within the capabilities of most microcontrollers to directly digitize, and some of 'em have pretty respectable amounts of DSP capability. So I'm thinking a low-pass filter to keep AM out of it and do impedance matching between the antenna and ADC, and everything else in software.

It's a "Hmm. This ought to work; I wonder if I can make it." effort.

I'm an embedded software guy for a living, so this falls in the category of junk-box projects for me.

John,

That is essentially what I am doing. My goal is to receive the signal with the lowest possible power consumption. So I am working with a very low power FPGA.

I plan to use a LVDS differential input as a comparator to produce a binary input to the FPGA. I am working on a frequency locked loop that will give me a sample rate of 240 kHz, 4x the carrier which will save having to do multiplies in a synchronous amplification approach. By multiplying the incoming stream by a complex rotating vector at 60 kHz which is just (1,0) (0,1) (-1,0) (0,-1), the input will be shifted to zero hertz as a complex pair. As you can see this is just inversions and adds with no multiplies. The phase can easily be obtained from this information.

I plan to sum the signal for a period that will give sufficient resolution to detect the changes in phase in the signal. I expect this will either be 10 Hz or possibly 30 Hz which would be a good clock rate for an LCD display.

The 240 kHz VFO will not be stable long term and these devices typically only check the WWVB signal once a day. So a 32768 Hz oscillator will be used to run the clock itself and the 240 kHz (slaved to the WWVB signal) will be used to measure the frequency of the 32768 Hz clock so it can be trimmed digitally. I might use trimmer caps, but it will likely be easier to trim using an NCO.

To use the LVDS input with no amplifier will require a strong signal. I am east coast so the signal is marginal. To get the highest voltage possible, I was thinking of working with a larger non-ferrite loop. I've made a frame about 2 foot in diameter which will have 16 turns of RG-6 coax to make it a shielded loop. This will give a voltage of about 0.2 mV if I can keep the Q close to 100. The 18 gauge center conductor of the coax will do well if it is solid copper (most RG-6 coax is copper coated steel).

I have a board I build that can be programmed to produce the 60 kHz WWVB signal. So I can test when the signal is too weak to be received reliably.

I just read that you are near Annapolis. I am not far from there on the other side of DC. lol Maybe I'll connect my WWVB generator to the antenna and see if you can pick it up.... when I get it working.

So is the above anything like what you are thinking?

Rick C.

To amplify a little: It occurred to me that 60 kHz is will within the capability of almost any microcontroller to directly digitize.

I'm therefore playing around with hooking a minimal antenna and front end onto a suitable chip, and doing all the requisite signal processing

as DSP on the chip.

Since the consumer devices I mentioned all use loopstick antennas, it seems like a reasonable starting point. I can, of course, fall back to a larger open-air loop if it proves necessary, but I want to try the bar antenna first.

Dunno how much will come of it, but it should be
fun trying.

Most of the difference between what you're doing and what I am is right
there; I'm figuring on using one of Microchip's dsPIC controllers
(mostly because they look to be up to the job, and I've got a couple
dozen around; leftovers from old projects).

I get a 12-bit 500 kS ADC on that, so I'm thinking a low pass filter to
keep out AM, and roughly 8-9x oversampling.

I may need to add an amplifier stage between the LPF and the ADC, but
I've seen DSP pull some amazing things out of the mud, so maybe not too.
We'll see. I'll upgrade the antenna first.

Other than that, I get 70 MIPS and single-cycle multiply-accumulates, so
there's some good DSP horsepower there. The chips were
designed to do audio DSP, but 60 kHz is a small enough stretch that they
can still handle it.

The algorithm details are much as you describe, modulo being written in
assembly instead of VHDL and 12 bits vs. 1.

The uC clock itself should give me enough stability to eventually lock
onto WWVB; at that point, I'll see how far I can push the accuracy.

Contra, is when each coil is wound in a different direction from the next to it. The reason for doing that is to reduce the interaction between the coils.

The FPGA will have each portion running at the exact clock rate required for that portion (including zero when not used), so I will be able to keep the power to a minimum. Plus, this FPGA is designed for very low power consumption and should be up to the job. Otherwise, an MCU would do the same thing, just with a lot of instruction fetching to make it all happen.

Your sample rate will be about twice mine so that is good. If you sample at 240 kHz (synchronous to the WWVB carrier) you can eliminate the multiplies altogether and drop the multiply unit, lol. At 480 kHz you can get away with a multiply every other sample. But I'm sure you are not trying to minimize the power consumption.

The 12 bit ADC can do you a lot of good, if your signal is large enough to use more than 1 bit. As I said, I am shooting for 0.2 mV at the input and that requires careful attention to detail in the antenna design. I don't think you will get anywhere near this from a ferrite loopstick so a preamp will be required. I have a design for a very low power cascode circuit using BF862 FETs. The gain is in the 80 dB ball park while presenting a very high impedance and a low capacitance to the input. If needed this would be a great circuit to use keeping the Q of the antenna high.

Just to mention, ferrite loopsticks are used because they are small. They produce a very small signal, but because the noise is dominated by environmental noise, it is not important to have a great low noise front end. Instead any amplifier does the job well enough so the loopstick typically works fine. But it won't do without the preamp.

The two problems with a WWVB receiver without a preamp is signal strength and selectivity. If you don't use a preamp you will be working with the same 1 bit on the input that I will have (if you are lucky, even getting 1 bit requires some feedback to eliminate DC offset on the input). Your programming in the DSP will get you selectivity. A synchronous amp working over a long period is essentially a *very* narrow band pass filter and will help eliminate much interference.

Rick C.

Hi
I am a bit mechanically dislexic but let's muddle on.

Starting a winding at the 6 o'clock position, going clockwise, when the first loop is complete in a same plane, spiral loop antenna, it is common to continue on clockwise for the 2nd loop and have a spacing of an inch or two between the the loops to get a 2nd loop a slightly shorter length (smaller Diameter) to reduce distributed capacitance in the loops.

Does contra series mean not to continue on clockwise but to make the next turn counter clockwise, and should one continue on with keeping the inch or two spacing, at the expense of reducing the Area of the Loop(s)?

Or does Contra Series eliminate the need for the inch or two spacing.

Same question(s) about a solenoid type of winding. Should there be spacing between each winding?

I think the above is all Contra Series so my next question is for a more detailed description of contra parallel

G'day loopers. A ferrite loop antenna has little "aperture". A loop antenna is constructed with a large diametre to give it "aperture". You can increase a ferrire loops aperture by using a long ferrite rod. Ihave butt glued two rods together and carefully rolled a collar of notepaper and araldite around the joint to strengthen it (essential). Or you can use the two rods coaxicaly and seperated by say 12 inches, wind coils over each rod and connect them so that they oppose or abet each other. As an experiment. I have made both types. The set up with the separated rods possess the deepest nulls I have ever seen in loop antennas. Happy looping VK2TTI

Re: [loopantennas] Ferrite bar antenna

Hi I am a bit mechanically dislexic but let's muddle on.

Starting a winding at the 6 o'clock position, going clockwise, when the first loop is complete in a same plane, spiral loop antenna, it is common to continue on clockwise for the 2nd loop and have a spacing of an inch or two between the the loops to get a 2nd loop a slightly shorter length (smaller Diameter) to reduce distributed capacitance in the loops.

Does contra series mean not to continue on clockwise but to make the next turn counter clockwise, and should one continue on with keeping the inch or two spacing, at the expense of reducing the Area of the Loop(s)?

Or does Contra Series eliminate the need for the inch or two spacing.

Same question(s) about a solenoid type of winding. Should there be spacing between each winding?

I think the above is all Contra Series so my next question is for a more detailed description of contra parallel

On Thu, Oct 6, 2016 at 5:08 PM, gnuarm.2007@...m [1] [loopantennas] <loopantennas@yahoogroups.com [2]> wrote:

The FPGA will have each portion running at the exact clock rate required for that portion (including zero when not used), so I will be able to keep the power to a minimum. Plus, this FPGA is designed for very low power consumption and should be up to the job. Otherwise, an MCU would do the same thing, just with a lot of instruction fetching to make it all happen.

Your sample rate will be about twice mine so that is good. If you sample at 240 kHz (synchronous to the WWVB carrier) you can eliminate the multiplies altogether and drop the multiply unit, lol. At 480 kHz you can get away with a multiply every other sample. But I'm sure you are not trying to minimize the power consumption.

The 12 bit ADC can do you a lot of good, if your signal is large enough to use more than 1 bit. As I said, I am shooting for 0.2 mV at the input and that requires careful attention to detail in the antenna design. I don't think you will get anywhere near this from a ferrite loopstick so a preamp will be required. I have a design for a very low power cascode circuit using BF862 FETs. The gain is in the 80 dB ball park while presenting a very high impedance and a low capacitance to the input. If needed this would be a great circuit to use keeping the Q of the antenna high.

Just to mention, ferrite loopsticks are used because they are small. They produce a very small signal, but because the noise is dominated by environmental noise, it is not important to have a great low noise front end. Instead any amplifier does the job well enough so the loopstick typically works fine. But it won't do without the preamp.

The two problems with a WWVB receiver without a preamp is signal strength and selectivity. If you don't use a preamp you will be working with the same 1 bit on the input that I will have (if you are lucky, even getting 1 bit requires some feedback to eliminate DC offset on the input). Your programming in the DSP will get you selectivity. A synchronous amp working over a long period is essentially a *very* narrow band pass filter and will help eliminate much interference.

Most of the difference between what you're doing and what I am is right
there; I'm figuring on using one of Microchip's dsPIC controllers
(mostly because they look to be up to the job, and I've got a couple
dozen around; leftovers from old projects).

I get a 12-bit 500 kS ADC on that, so I'm thinking a low pass filter to
keep out AM, and roughly 8-9x oversampling.

I may need to add an amplifier stage between the LPF and the ADC, but
I've seen DSP pull some amazing things out of the mud, so maybe not too.
We'll see. I'll upgrade the antenna first.

Other than that, I get 70 MIPS and single-cycle multiply-accumulates, so
there's some good DSP horsepower there. The chips were
designed to do audio DSP, but 60 kHz is a small enough stretch that they
can still handle it.

The algorithm details are much as you describe, modulo being written in
assembly instead of VHDL and 12 bits vs. 1.

The uC clock itself should give me enough stability to eventually lock
onto WWVB; at that point, I'll see how far I can push the accuracy.

11590. Re: [loopantennas] Ferrite bar antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-10-07 03:20:26 UTC
From: Andy ZL3AG
Topic: 11575 Message: 11590

The best EVER loop I have ever used for broadcast band reception was the G.S. Maynard designed "Q Multiplier and Spiral Loop Antenna" as described in the March 1981 issue of the British magazine "Practical Wireless".

I built one using just normal "hookup" wire, with hinges on the 7 wooden arms so it would fold up (like an umbrella) and I used to go mobile DXing all over New Zealand in my race/road 1220cc '73 Mini with that antenna stored across the back seat of the car, and a Racal RA17L receiver strapped into the front passenger seat with the full racing harness.

The tuning was so sharp you could peak it on either sideband of an AM broadcast signal and you could actually hear the audio peak move around in frequency as you carefully tuned it across the signal - the tuning capacitor needed multiple 10:1 (??) drives on it to do this.

If you could build one for 60kHz, you'd be onto a winner.

Cheers,

Andy

Agreed on all counts (especially the 1-bit part). I'm also hoping (haven't done the detailed analysis yet) that I can use the headroom that 12 bits and 8x oversampling gives me to do the DC offset in software as well. So, I'd get the same 1-bit resolution as you, but it might still be enough.

If not, because I'm not particularly interested in power consumption, a low voltage op-amp stage or two will be the first preamp I'll try, but I'll probably try a big loop before that.

The Q-multiplier that Andy ZL3AG suggests is an idea I haven't considered; have to think about that. Thanks, Andy.

My pleasure. I've guessing the WWVH signal is fairly low bandwidth. :^)

I'm not familiar with a Q-multiplier. I can't say how much that will help. But it sounds like a very high Q filter. That is what your DSP calculations will do. So the Q-multiplier may be redundant.

The 1 bit signal using a 12 bit ADC means the signal is not large enough to span a full bit. If you don't provide some means of offsetting the DC point before the ADC input the signal won't cross any thresholds in the ADC and you will get a constant reading. Another way to make that work is to provide a dithering signal that adds in an aperiodic offset that is enough to get the signal to change the ADC sample value. The amount of the offset is different for each sample and so some values will cause the threshold to be crossed, but others won't. Because the dither is aperiodic the energy is spread over the spectrum and is filtered out easily.

The way I am doing it is to feedback the the inverse of the value measured through a low pass filter and summed into the input. This will result in the signal to be high half the time and low half the time, meaning the average input will be perched right on the threshold compensating for any DC offset in the input.

If you use a larger loop, it will need to be pretty large. The loop I have analyzed (2 foot diameter, 16 turns, 18 gauge conductor) will give a signal that is less than one bit of your 12 bit converter assuming it uses a 3.3 volt reference. A much larger signal would be better in your case. I believe the signal strength formula is linear with number of turns, but proportional to the area of the loop (diameter squared). So for a given length of wire (and resistance which impacts the Q), your best bet is one large loop. I have 100 feet of coax which I might first try as one huge loop if I can hang it in my living room cathedral ceiling. That will give a 4 times larger signal as 16 turns on a 2 foot frame. It won't be very round so the nulls won't be very good, but it can't be steered anyway, so the nulls aren't likely to be much use anyhow. lol

Yes it is; it's essentially an active tuned circuit involving the antenna as an inductive element. Like tuning your loop, but with active components (I'm going to guess a FET would be best, but am working off very old memories about Q-multipliers) involved too. The advantage, for this application, would be quite a bit of selectivity at the very front end.

Yes, I know the theory of sub-bit noise sampling.

I'll start by hoping I can get enough natural noise; if not, a high-speed digital noise source from one output line run through a low-pass filter/attenuator should do the job.

I need a minimum 800 uV of noise out to 480 kHz (or 240), so a few RC stages hung off of an SPI port clocked at 10-15 MHz and fed with random data should make a decent enough noise source if necessary.

G'day all again. A Q multiplier, essentialy an active device that introduces a suitable amount of positive feedback, lke the old regenerative recivers. Too much feedback and the system goes into oscilation (spelling ugh). Careful design is required. Regards again VK2TTI

Topic: 11596 Message: 11596

Hi
FYI and a request for comment(s) and constructive criticism
73 Jordan ve7jjd

New Spell checked

Small Wideband Magnetic Loops
Hi
A first cut to answer the following question(s).
[shortwave-radio] I am in a 14th story high apartment 38 North -77 West with no balcony just one window facing 55 degrees NE 120 ft elevation I would like ideas for a stealth antennas or for websites to guide me for options for frequencies 0 kHz through 2 MHz for the SDRPlay.
James Campbell cmpbll_jms@yahoo.com [shortwave-radio] <shortwave- radio@yahoogroups.com>

I have been doing a lot of researching and reading for antennas for similar requirements of a Senior Citizens SWL/Scanner Club in a 19 story Assisted Living apartment building with a listening station in the 19th floor Lounge, as well as for individual Members on some lower floor balcony. Mine being on the 8th floor.
Several things come immediately to mind:
a) There is no such thing as a single design "super dooper" antenna for all frequencies!
b) All antennas are some form of a tuned circuit, resonant at one or more frequencies, primary and it's harmonics.
c) The laws of physics/science are the same for both transmitting and receiving; with transmitting calling for more robust components to handle large amounts of power.
At this time I will point out that I will be quoting and paraphrasing from many sources with little or no referencing to same.
In Gordon Darlings article on the Sony ICF 2010 he refers to not presenting a receivers front end to raw signal from DC to Multi Giga Cycles/Herz, noise and signal combined. He recommend some form of bandpass filtering, a Tuned Antenna and/or an Antenna Tuner.
This article will break down receiving requirements into three areas in conjunction with the three basic Bands covered by conventual multi band receivers.
Shortwave HF 1700 KHz to 30 Mhz
MW/LW 60 Hz to 1700 KHz
Scanners VHF/UHF 30 MHz to Multi GigaHz.
VHF/UHF wideband Antennas are small enough to place in/near a window or hang a couple of feet outside a/the window. Thus this all that I will present at this time. Take a look at the Base Scanner Antenna Radio Shack 20-014 NOS in BOX Police All Band Antenna to hang out the window.
For the remaining I will break things down to Passive vs Active.
Most SWL hobbyists receivers have two internal/external antennas; a "Long Wire" telescoping Whip and and an internal ferrite Coil.
External Antennas are made to replace and/or to compliment these antennas.
Passive Antennas
a) An untuned Long Wire, clipped or inductively coupled, to the Whip or bypassing the Whip via an external antenna Jack. Wire on a reel: Sangean ANT 60, Sony Compact AN 61, Redsun

RA-100, Tecsun AN-06, RADIO SHACK SHORTWAVE ANTENNA MODEL 278-1374A
b) A Small Wideband Magnetic Loop tuned or untuned, inductively coupled to the receivers internal loop and sometimes to the receivers external antenna jack. Here I am thinking about store bought Loops like: Select A Tenna; Tecsun AN-200 AM/MW Rotatable Tunable Loop
c) A Long Wire dropped over the window/balcony with Balun mounted just outside the window sill, with coax low noise pickup to the the receiver system, in this case an Antenna Tuner being considered as part of the Receiver System. This to get the antenna out of the noise fields of the interior of the apartment/building.
d) More complicated is expanding on b) above with a custom build loop commensurate with your construction skills, operating/listening procedure(s) and esthetics taste(s), from one of hundreds of Loops described in/on the Internet. The problem here is that there is precious little specific designs for LW and HF.
However For LW use MW designs with more turns, (and possibly more capacitance in the variable capacitor) a longer length of wire. One can have less distance seperating each turn which increases the distributed capacitance which in the LW case is benifical. A solenoid wind is probably better/easier than a spiral wind where each turn is smaller thus reducing the overall area of the loop. The longer wire adds to the overall mass and the use Litz as opposed to speaker wire/zip cord should be considered.
Rules of thumb for Loop construction are as follows:
a) length of wire one tenth of full wave length keep the antenna to act as a loop
b) Large overall Area
c) Low inductance loop
d) Circular better than octagon better than triangular better square better than rectangular
e) Spiral better than Solenoid (side by side)
f) Space between windings to minimize distributed capacitance
Generally a tunable, rotatable loop, adjacent to the receiver. However look towards a Loop at/in the window and a remote tuning mechanism adjacent to the receiver.
It is here that I can point out some unique solutions such as the remotely tuned Carpet Loop, and a remotely tuned Loop in/on the window or on wall space between the vertical steel support columns, (every little bit counts).
One should seriously consider building/buying several antennas and a switching/combining system so one can easily switch to the antenna performing the best with actual conditions of the moment. This will also apply to the more complex active antennas as well.

The use of Transmitter grade Coax Switches and Coax to whatever Adapters is a tad expensive but easy to implement. DIY with parts (no shielding or impedance matching) from Radio Shack would suffice. On EBAY you can find assembeled circuit boards for Antenna Switching and Antenna Combining.
---
http://www.ebay.com/itm/162168680440?_trksid=p2057872.m2749.l2649&ssPageName=STRK%3AMEBIDX%3AIT 1-400Mhz or 1-30Mhz (HF) 4 Way Antenna Splitter for RX with RF amp. Very useful device for RX antenna splitting between 4 different receivers with more gain. This Seller also made me a non amplfied reverse Board 4 different antennas to one receiver.
---
http://www.ebay.ca/itm/KIT-4-position-antenna-switch-/252339909226?hash=item3ac0a1726a:g:cTAAAOSwnTJW~kw1 KIT 4 position antenna switch
---
See further below for a passive HF Small Single Turn Magnetic Loop Antenna

http://www.kr1st.com/swlloop.htm

Active Antennas MW/LW
Glorified Whip/Longwire
Combined Whip & Tuning Amplifier, adjacent to the receiver; better yet a remotely tuned Antenna element in/on the window with Tuning element adjacent to the receiver. There are several commercially available as well as DIY Kits. The problem here is that although they act as a bandpass filter they amplify the noise as well as the signal in the band passed on to the receiver.
http://www.universal-radio.com/catalog/sw_ant/2206.html The Sony AN-1 active antenna provides good reception over the range 150 kHz to 30 MHz (longwave, medium wave and shortwave). The outdoor antenna amplifier module with 59 inch (1.5 meter) telescopic whip can be connected anywhere outdoors or even inside a window or attic. The Sony AN-1 includes 39 foot (12 meters) coaxial feed-line which connects to the compact control box. Output from the control box is a mini jack. Two output cables are supplied: one to alligator plugs and one to a mini plug. The AN-1 can even be used to enhance long wave or medium reception on radios that do not have an external jack. Just place the supplied ANC2 antenna module behind your portable radio to inductively transfer the radio signal into your radio's built-in antenna.
Indoor adjacent to the receiver include the following: MFJ 1020; MFJ 1024; Stoner Dymek DA 106D; Palstar AA 30;
It is here that one should start exploring the use of Antenna Noise Canceller such as the MFJ-1026 and Timewave ANC-4.
Small Amplified Loops
Basically the same overall construction/design of passive loops but adding a wide band, low noise amplifier in the tuning and lead-in subsystem.
a) At the remote Antenna with remote Varicap tuning adjacent to the receiver
b) At the Remote Antenna with no varying of the resonating capacitance
c) Adjacent to the receiver with variable capacitance
d) Adjacent to the receiver with no varying of the resonating capacitance
---
Commercial Loop antennas are the:
Sony ANLP-1; C.Crane Twin Coil Ferrite AM Antenna;
KESTREL-DEGEN-DE-31MS-MW-SW- Active Loop Receive Antenna;
Mini-Whip HF, VLF active antenna, 10kHz to 30MHz
http://www.ebay.com/itm/Mini-Whip-HF-VLF-active-antenna-10kHz-to-30MHz-/201539443391

SWL HF Loop extracted from http://www.kr1st.com/swlloop.htm
A Magnetic Loop Antenna for Shortwave Listening (SWL)
Now that were on the downward slope of sunspot cycle 23 (2004) you may have noticed that some of your favorite broadcast stations don't come in as strong as they did a few years ago. This is especially apparent on weaker DX stations. The whip on your shortwave receiver used to be sufficient to pull in some good DX, but now you find yourself looking for something better.
Maybe you have been thinking, or even have already tried, putting up a wire antenna. This may be a great solution if you live in a reasonably quiet area, noise wise, and your shortwave receiver doesnt easily overload in the presence of strong signals. Perhaps you live in an apartment or are situated where installing a wire antenna is simply not

feasible. Or maybe you are looking for something that offers a bit more mobility so you can take it into different rooms of your house. Consider the small single turn magnetic loop antenna if any of the above situations apply to you.

Small Single Turn Magnetic Loop (SSTML)

The small single turn magnetic loop (SSTML) antenna consists of a single winding inductor, about 3 feet (1 meter) in diameter, and a tuning capacitor. A second loop, which is one fifth of the diameter of the large loop, is connected to the feedline and this small loop is positioned in the large loop on the opposite side of the tuning capacitor.

Magnetic Loop Antenna

The SSTML has some very interesting properties:

a) It has a small footprint. The loop I describe here looks like a circle in the Vertical plane and is just a little over 3 feet (1 meter) in diameter.

b) It is a rather quiet antenna. It doesnt pick up as much man-made noise from nearby sources as a wire antenna would in the same situation.

c) This antenna is somewhat directional, which can benefit you in two ways. You can either aim (rotate) the antenna for maximum signal strength, or for minimum noise pickup. I prefer to do the latter, and heres why. This antenna has what is called a deep null on each side of the antenna, the broad sides, meaning that signals coming from that direction will be attenuated quite a bit (30 dB is an often-quoted figure). However, this is mostly true for signals we receive directly, like noise sources, and not so much for signals from broadcast stations coming to us through skywave propagation. I aim the antenna for minimum noise pickup, which results in the best signal to noise ratio. In some situations it is quite possible to fully tune out a noise source such as a TV or computer monitor.

d) Since this antenna is really a tuned circuit, it also acts as a preselector. It only receives well in a narrow bandwidth of a few hundred kilohertz (kHz). The antenna requires retuning if you change the frequency on the radio by a hundred to two hundred kHz. This may sound like a disadvantage, but if you have ever tried a long wire antenna on a rather sensitive receiver, you probably have noticed that your receiver may get overloaded, resulting in hearing multiple stations at once or hearing broadcast stations on frequencies where there really arent any. This may make it impossible for you to pull in that DX station youre really interested in or even make listening to a strong broadcast station rather unpleasant. This antenna will help prevent overloading your receiver.

When you search the World Wide Web for magnetic loops, you usually run into magnetic loops meant for transmission in the upper ham bands, perhaps 14 MHz and above. To be able to transmit on these loops youll have to follow stringent design rules in order to maximize the efficiency of the loop. If youre interested in a receive-only loop, then the design rules become very relaxed. Theres no need for large diameter tubing and neither for a low loss capacitor to successfully build a loop antenna. On this page I will present a description of my SWL loop.

Main Loop

I built the main loop of my SSTML from quarter-inch diameter soft copper tubing. Its rather flexible and keeps its shape nicely after being formed into a circle. Other conductors /wire can be used. The aim is to have low inductance, maximum surface area of the conductor(s), large area, and low distributed capacitance, to establish a high self resonant loop in the 20+ MHz range and a large variable capacitor to bring the resonant frequency down. Litz wire, Flexweave and low gague speaker/zipcord will all work well.

Capacitor Tuning

A multi stepped variable capacitance preferably remotely controlled to increase capacitance/tune the loop. A multi section variable tuning capacitor is the one most commonly used however switching in a bank of fixed capacitors is also effective.

When the loop is constructed and tuning capacitance set to minimum you can test for maximum

useable frequency. You can test it by holding the whip antenna of your shortwave receiver very close to the upper half of the loop and tune the receiver slowly in the 15MHZ to 20MHZ to find a noise peak coming from your receiver, and perhaps you’ll even be able to hear the WWV station. There will definitely be a peak in the noise, when tuning through the resonant frequency and past that the noise will decrease again.

Coupling

The next step is to build the coupling loop that will pick up the energy generated in the main loop and offer it to the receiver.

When you look at the many designs of magnetic loops on the internet, or in various other publications, youll notice that there are different ways to construct coupling loops. Some dont even use a loop, but a gamma match to connect the magnetic loop to the feedline. However, this would require another variable capacitor. Other designs use a coupling loop built from coax cable, and the center conductor and braid have to be connected in a certain way to minimize noise pickup. Ive (kr1st) experimented quite a bit with different types of coupling loops, including complex ones built from 4 pieces of coax, but I noticed no difference in performance compared to the simple wire loop. So lets keep this simple.

I constructed the coupling loop from solid #14 house wire. The size of the wire is not critical at all, just pick a size of whatever you have laying around that will keep its shape once mounted. The length of the wire should be about 2 feet if the circumference of the main loop is 10 feet. In other words the length of the wire for the coupling loop is one fifth of that of the main loop.

Construction of a Coupling Loop

Bend the wire in the shape of a circle and solder one end to the center conductor of the feedline (coax) and the other end to the braid. Use some electrical tape or shrink tubing to cover the exposed parts. On the other end of the coax you can attach a connector that will fit into your receivers external antenna jack. One of my favorite receivers, a Radioshack DX-398, uses a 3.5 mm phone jack that is easily obtainable at Radioshack. Solder the center conductor to the tip of the plug and the braid to the sleeve. Check the manual of your receiver to find out what the correct plug is and how the coax needs to be connected.

Once the coupling loop is completed you can attach it to the support frame pipe with a few wire ties. The coupling loop needs to be mounted on the opposite side of the tuning capacitor, which is the bottom of the main loop.

Feedline

The feedline of choice is coax for this antenna. This is mainly a choice of convenience, as you can route coax much more easily than balanced feedlines. Which type of coax, or the length, doesnt matter. You can use RG-58, but if you have only TV coax (RG-59, RG-6) available, then that will work just fine. Use whatever you have.

The Completed Magnetic Loop

You can test the loop by connecting it to your receiver and trying to determine the upper and lower tuning limits.

First, make sure all trimmers on the tuning capacitor are open.

To find the lower limit, connect a receiver to the loop and set capacitance tominimum. Turn the receiver on and tune it up through 5 MHz. If you can select a step size on your receiver, select 5 kHz, and make sure the receiver is in the AM mode. In case the receiver has different filter settings, choose the widest filter available. Now tune the receiver up in frequency and listen to the noise level. At some point you will notice that the noise increases. Write down where you think the noise is at a maximum. On my loop that is around 5.3 MHz.

Now, to find the upper limit, tune the receiver to 25 MHz and tune the receiver down in frequency in 5 kHz steps and write down where you find the noise to be at a maximum. At

23.2 MHz I found the maximum noise on my loop.
You now know the tuning range of your loop. My loop tunes from the 49 meter band all the way up to the 13 meter broadcast band. This includes the 40, 30, 20,17 and 15 meter amateur radio bands. Your loop may have somewhat different values for the lower and upper limits depending on the range of your tuning capacitor.
Fine Tuning (optional)
The loop will probably cover all the shortwave bands youre interested in without any fine tuning. However, if you find that the loop does not cover a band you want near the upper or lower tuning limit, it may be possible to add that band with some fine tuning. Keep in mind that if you raise the upper tuning limit, you will also raise the lower tuning limit and vice versa. Changing the tuning range of this loop antenna is like moving a sliding window over the shortwave bands. If youd like to raise the upper limit, youll have to lower the minimum value of the variable tuning capacitor.
You can lower the lower limit somewhat by using the trimmers on the variable capacitors . First tune the receiver to the lower limit you found earlier. Now close the trimmers with a screwdriver. This will add about 20 pF (pico-Farad) per gang/section to the total capacitor value. Not much, but it may be just enough. After you closed the first trimmer, tune the receiver down in frequency and find the new lower limit (tune for maximum noise). If thats not enough, close another trimmer and find the new lower limit. Hopefully that will bring the lower limit to where it needs to be. Keep in mind that the loop will probably not tune much lower than 5 MHz. Also remember that by lowering the lower limit you also lower the upper limit. This may mean that though you gain one band at the lower end, you may lose two or three bands at the upper end. Youll have to decide which is most beneficial to you. Since were on the downward slope of the sunspot cycle (2004), it may be more beneficial to lower the lower limit than raise the upper limit of the loop.
Of course you can try all kinds of combinations of closing trimmers and/or disconnecting capacitors. This will give you a wide variety of ranges, but can easily drive you crazy. Try to remember the sliding window principle. Adding capacity (i.e. closing the trimmers) will lower the lower and upper limits. Reducing capacity (i.e. disconnecting a capacitor) will raise the lower and upper limits.
Results
So how good is this loop, anyway? Compared to the built-in whip antenna, it may very well be the difference between copying a signal comfortably or not hearing it at all. Consider the following recording:
Choose Sample Recording (MP3 200kB) or Sample Recording (WAV 1.4Mb)
This is a 12 second recording of a part of a conversation (QSO) between amateur radio operators in the 20 meter band (14 MHz.). The receiver is a DX-398 portable. The loop was positioned right next to the receiver. For the first 4 seconds I used the loop antenna. Then I switched to the whip antenna for the next 5 seconds, and then switched back to the loop. As you can hear, the difference is dramatic. The signal is virtually inaudible on the whip, but very clear on the loop.
You can see an example of how well it can reduce noise from nearby noise sources on my random wire vs. magnetic loop page. I compared a random wire antenna strung throughout an apartment to a magnetic loop antenna. Even though the loop used in that example was built also for transmitting, the results are the same when it comes to receiving. By pointing the broadside of the loop at an offending noise source, like a TV or computer monitor, the noise can be effectively reduced.
You may notice that due to the pre-selecting properties of the magnetic loop your receiver will be less likely to overload, especially compared to a random wire antenna. This will greatly enhance the enjoyment of shortwave listening on a sensitive receiver.
Conclusion

It does take some time and effort to build this loop, but Im confident youll be pleased with the results. This loop took me about an afternoon to built, not including the tripod. Sure, stringing up a random wire antenna is a whole lot easier and quicker, but the results can be far less than desirable, especially in a noisy apartment setting.

It may sound somewhat complicated to build this antenna, especially the tuning section, but it really isnt. In fact you dont have to go through the tuning procedure at all. Chances are that even without fine tuning the antenna already covers all the bands youre interested in. Its a fun antenna to build and it gives you a greater sense of accomplishment than just stringing up a random wire. Youre actually building an antenna.

I hope youll enjoy your loop as much as I enjoy mine. Dont let the declining number of sunspots keep you from enjoying your favorite shortwave radio show. If you have any questions or suggestions, please do not hesitate to drop me an email.

11597. Receiving/Receiver Accessories

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-10-12 22:03:23 UTC
From: jjdobrikin@...
Topic: 11597 Message: 11597

Hi
This taken from my use at Sony ICF 2010 Yahoo Group.
Now submitted to this Group.
Thanks
73 Jordan ve7jjdb

Hi

I have been surfing the Files and Photos and found in Photos some Loop antennas homemade and commercial as well as some interesting stands to position the radio for easier use.

This leads me to a general question, what accessories are being used, or have been used, and how effective are/were they??

I am thinking past small commercial loops active and or passive. Although i am interested in the C.Crane Twin Loop.

I am very interested in the use of the big expensive commercial loops.

Other accessories include:
Antenna Tuners
Preselectors
Noise and Interference Reducers (RF)
Active Antennas: Whip
Artificial Ground
Speech Enhancer

Thanks
73 Jordan ve7jjd

11598. For Sale are 2 each 7.5" X 7.5" FSL antennas

Yahoo group: loopantennas (2013 — 2017)

From: everettsharp@...
Topic: 11598 Message: 11598
Attachments: 2 described; binary payloads are missing from this source WARC

I have for sale 2 each 7.5" X 7.5" FSL antennas. The FSLs were wound in a 2 coil Polydorff configuration. The 2 windings were wound with 660/46 Litz wire and the variable capacitors are the high Q, 2 gang, Russian units, with a 3:1 turning ratio. I added a band switch so the second gang can be switched in for extended band coverage. Both FSL are mounted on a Lazy Susan base.

Band (1) tunes from 2,000 to 420 KHz and Band (2) tunes from 575 to 275 KHz. The tuning is sharp and the rotational nulls are quite sharp. Both FSLs are setup for induction coupling only.

I am asking $375 each, plus what ever the shipping cost would. Below is a pictures of one of the FSLs. If interested please contact me off list everettsharp@....

I have built and sold several FSLs, however, these two will be the last I build for sale, as I have used up all of the ferrite I had on hand to build them and most of the sources of supply for the Russian ferrite bars have dried up. Each of the FSLs have around $150 in material cost and about 20 hours work each. These are one of a kind and can not be bought anywhere else.

Everett N4CY

Problem.
In modern building and houses it is difficult to set up and antenne for Hams specially indoors.
If a balcony can be used than there are more options bud indoors is a challenge.
You can experiment with the active capacitive whip and ferrite rod antennes to find the best compromise. Every indoor situation is different try it what is the best.
Want to receive the spectrum from 100 KHz up to 30 MHz and listen the SW broadcast stations.
My focus was to have an active indoor WB antenne and homemade. Some results and thoughts.
Experiments are done with the active capacitive antenne and the ferrite loops.

Capacitive mini whip antenne.
I found thad a lot of domestic noise is coming from the electric field like sparks and switching spikes from PC and other systems in modern houses.
The WB capacitive antenne was not very us full indoors because of the noise pick up, and is only a good performer if it can be placed outside away from the building. An option is place the antenne on a pipe boom outside if you can open an window
Nice is the wide band characteristic up to VHF.
An good source is the book “Aktive Antennen”writen by “Eric T Red and Reinhard Birchel DJ9DV”, Beam-Verlag ISBN 3-88976-043-0 with amateur and professional antennen examples.

One winding closed loop active antenne.
Another option is a closed one winding loop on the window class. It can be aluminium tape or strip or copper pipe.
In the files there is a doc of the 120 active loop antenne. The size can be adjusted for the window.
Be aware thad an problem can be if the windows are made from double class,
There can be a coating on it of a metallic film to reduce solar radiation and also on the edge an aluminium circular closed strip with keep the two glass separate.
This form a magnetic closed loop.
Koppel it with a pick up loop and see if there is a signal EXPERIMENT....

This type off widows have a signal los the film is a static screen and the aluminium strip shorted the RF field.

The only solution is experiment with the options and keep the best.

Hi

From Yahoo Group Prime Time Shortwave

Note his Station Line Up.

I am interested in other SWL/MWLer's and what units you are particularly fond of.

I am especially interested in HF Loops Home Brew or Store Bought.

Thanks in advance

Kiwa - High Performance MW Air-Core Loop Antenna
High Performance MW Air-Core Loop Antenna by KIWA
http://www.kiwa.com/kiwaloop.html

Palomar Engineers Loop Antennas LW-MW-SW2
Palomar's Loop Antenna gives superb performance on the AM medium-wave broadcast band. The loop rotates and tilts to give deep nulls so you can eliminate local interference. It also allows you to null out a station and listen to another one on the same frequency.
http://www.palomar-engineers.com/Loop_Antenna/loop_antenna.html

The Quantum loop antennas, now V2.0

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11604. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-01 13:06:28 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11604

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11605. DXing Back to our root(s)

Yahoo group: loopantennas (2013 — 2017)

From: Jordan Dobrikin
Topic: 11605 Message: 11605

Hi

DXing Back to our root(s).

http://www.qsl.net/ko6bb/perfect-radio.html

*"THE SEARCH FOR THE PERFECT RADIO". 73 de Phil KO6BBIf it's more than 1dB above the Noise Floor "IT AIN"T DX"! *

The Perfect Radio, a contemplation.

*13 Apr 2000 About 1953 (10 years old) I was given an old console radio which at first didn't work. But with time and messing with it I actually got it to play. To this day I don't know how as I knew absolutely nothing about them. This was also the first set I ever heard "Shortwave" on. I didn't know anything about it but knew those stations had to be "awful far away" if they said things like "BBC London", "Quito Ecuador" etc. This was just the first of many (probably hundreds if the truth be known) radios that have passed through my hands over the years. The search for "THE PERFECT RADIO" continues to this day. WHAT WOULD A PERFECT RADIO BE? Here are my thoughts on the matter. 1. It would have sensitivity that would allow it to receive absolutely any station that was on the air regardless of atmospheric or distance attenuation. If I wanted to hear CAAMA Radio, Alice Springs Australia on 2310kHz, at high noon my local time, it would receive it. *
*2. The selectivity would be such that it would eliminate all interference from all undesired stations, whether they were 5kHz off frequency or on the same frequency as the station I want to hear. If there were 4 stations on the same frequency at the same time it would select the one I want to hear and reject all others. *
*3. It would be immune from all sources of interference, static, computer hash or atmospheric fading. *
*4. If a station has "muddy" audio it will clean it up and make it CD quality. *
*5. The radio would translate upon demand. If a station was broadcasting in Arabic and I wanted English it would do the translation, accurately and clearly. *
*6. It would sense your desires. If you wanted to hear Voice of Russia in English it would sense your desire and automatically tune itself, adjusting volume, tone and language to suit you. *
*7. The radio would automatically log the station, prepare the reception report and do follow-up reports as needed. *

*8. It would do all this with just a 2 foot whip antenna to preclude having to set up large, bulky, unreliable antenna systems. The perfect radio? NOT! Just think how boring SWLing would be if our equipment met all the

above criteria. If we didn't have to put up with the challenges and vagaries of the Ionosphere, the interference from other stations, the noise of thunderstorms, the uncertainties of unknown (to the listener) languages, the limitations of sensitivity and selectivity, the unexpected tube or transistor blowing out, the antenna being blown down and all the other little surprises our hobby holds for us. *

*NO, the perfect radio is the one I have on the table, or the one I will acquire next week or next year in "THE SEARCH FOR THE PERFECT RADIO". 73 de Phil KO6BB If it's more than 1dB above the Noise Floor "IT AIN"T DX"! *

11607. Magnetic Loop augmentation

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-06 03:13:19 UTC
From: Jordan Dobrikin
Topic: 11607 Message: 11607

Hi

Many SWL/DXers with some type of outdoors passive wire antenna(s), use some type of tuneable, pre-selection, active or passive, between the antenna and the receiver, for improved performance.

My question is in respect to Magnetic Loop Antennas both active and passive. Will pre-selection, active or passive be benefical?

From: Jordan Dobrikin
Topic: 11608 Message: 11608

Hi
Thanks for a timely response.

What you have described is the basic standard use and procedures of passive and active MW/HF Magnetic Loops.

The Sony and Degnen electronics are not really pre-selection they are there to tune the loop and amplify the signal to the receiver.

What I am exploring is placing a "tuneable preselector" passive or active between these antennas and the receiver.

Same question(s) as to the passive Loops that have an "Antenna Output" connector to output to a receiver; hence in this query this output feed a "tuneable preselector", between the antenna and the receiver.

The key here is "tuneable" as I know many DXers put a wide band low noise, preAMPLIFIER, between Antenna(s) and receiver(s)

11609. Re: Magnetic Loop augmentation

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-06 18:50:50 UTC
From: max.merli@...
Topic: 11607 Message: 11609

Good questions; i suppose it is more about wideband active loops because tunable loops are, by definition, already tuned to a very narrow band. However, even in the case of a tuned loop, i reformulate the question: how efficient is the suppression of out of band signals compared to a band pass filter?

11610. Modify C.Crane Twin Coil Antenna to HF???

Yahoo group: loopantennas (2013 — 2017)

Hi

To the antenna gurus.

I am exploring the possibility of modifying the C.Crane Twin Loop Antenna to HF, 3 mHz to 0+ mHz.

This Link to the Patent will show Schematic and Block Diagram.

The Patent Text indicates that it possible.

Help and or constructive criticism is solicited.

Twin coil antenna
US 6529169 B2
Abstract
A ferrite core antenna having two spaced signal pick-up coils coupled through a transformer so that the signals from the two coils are additively combined in the primary of the transformer. A variable capacitor connected to the two coils tunes the antenna to selected frequencies. This results in amplification of the signal.
Images(5) Patent Drawing
Claims(13)
What is claimed is:
1. An antenna for a radio receiver comprising a ferrite rod; spaced coils wound about the ferrite rod; a variable capacitor element connecting each coil together; and a combiner connecting each coil together, the combiner additively combining out-of-phase signals induced in the coils by received radio signals so as to provide an output signal corresponding to the sum of

the out-of-phase signals in the coils.
2. The antenna of claim 1, wherein said combiner comprises a transformer.
3. The antenna of claim 2, wherein the out-of-phase signals from the coils are connected to opposite ends of a primary winding of said transformer, and said output signal is supplied from a secondary winding of said transformer.
4. The antenna of claim 3, wherein said coils, said transformer and said variable capacitor form a resonant circuit which is tuned by said variable capacitor.
5. The antenna of claim 4, wherein said variable capacitor has a capacitance value which is electronically variable.
6. The antenna of claim 5 further comprising an amplifier for amplifying the output signal and for supplying the output signal to the radio receiver, and a variable voltage source connected to said variable capacitor for tuning the antenna to selected operating frequencies.
7. An antenna for a radio receiver comprising a ferrite rod; spaced pick-up coils wound about the ferrite rod, signals being induced in the pick-up coils by received magnetic fields in the ferrite rod, the signals being of opposite phase; and a combiner connected to the coils for additively combining the opposite phase signals induced in the coils to provide an output signal corresponding to the sum of said opposite phase signals.
8. The antenna of claim 7, wherein said combiner comprises a transformer.
9. The antenna of claim 8, wherein the opposite phase signals from the coils are connected to opposite ends of a primary winding of said transformer, and said output signal is supplied from a secondary winding of said transformer.
10. The antenna of claim 9 further comprising a variable capacitor connected to the pick-up coils, the pick-up coils, the transformer and the variable capacitor forming a resonant circuit, and the variable capacitor tuning the resonant circuit to selected frequencies.
11. The antenna of claim 10, wherein a first one of said pick-up coils has one end grounded, another end connected through the primary winding of said transformer to a second one of said pick-up coils, and said second pick-up coil is connected said variable capacitor.
12. The antenna of claim 11, wherein said variable capacitor is an electronically variable varactor diode. electronically variable varactor diode.
13. The antenna of claim 12 further comprising an amplifier for receiving the output signal from said transformer and for providing an amplified output signal; and a variable voltage source connected to the variable capacitor for tuning the antenna.
Description
This application claims benefit of Provisional application Ser. No. 60/216,267, filed Jul. 6, 2000.
TECHNICAL FIELD
The invention relates to an active ferrite core radio receiver antenna combined with an inductive and capacitance network for receiving and conveying signal energy between the active antenna and receiver. The active antenna comprises a resonant circuit which is electronically tunable to a

frequency of interest.

BACKGROUND OF THE INVENTION

Ferrite core antennas are widely used as antennas for radio receivers, particularly for AM broadcast band radios, to increase radiation resistance over that simple Hertzian dipole antenna. This is done by forming the conducting element of the antenna in a coil or loop, and placing a ferrite body inside the loop. The ferrite has the effect of concentrating and intensifying the received magnetic field inside the loop. This is the result of the high permeability, μ, of the ferrite material. The incorporation of ferrite into the antenna coil is most easily accomplished by winding the antenna coil around the ferrite rod.

The use of a ferrite rod increases the loop's radiation resistance by a factor of μe 2, where μe, is the ferrite's effective magnetic permeability. Typically, for frequencies in the 100 to 2000 kHz range, the value of μe for typical ferrites is from about 100 to about 10,000. Thus, for a value of μe of, e.g., 1,000, ferrite can increase the antenna's radiation resistance, over a Hertzian dipole, by a factor of 1,000,000.

The ferrite core or rod itself tends to absorb some of the signal power. This represents the work done in “flipping” the alignment of the magnetic domains inside the core with each signal element. This ferrite rod “ferrite resistance” adds resistance in series with the antenna. Even with this added resistance, the antenna's resistance is typically just a few ohms, or even one ohm or less. However, in operation, the antenna must be coupled to a large impedance of the receiver electronics. This is usually accomplished by adding a capacitor to turn the antenna loop into a resonant circuit. However, when a signal enters a ferrite rod antenna that is tuned to resonance with a coil and capacitor, the magnetic lines of flux begin to saturate. This is due to sympathetic resonance. Sympathetic resonance is much like setting two guitars close to each other and plucking the string on one of the guitars. If both strings are tuned the same, the plucked string sound waves will cause the corresponding string on the other guitar to vibrate identically. When this saturation occurs in a ferrite core antenna, the ferrite rod antenna takes on polarity, much like a standard magnet. Ferrite antennas of the prior art have only one pick-up coil, and this coil receives the sympathetic resonance from only one-half of the ferrite rod. This results in loss of efficiency and limits the signal-to-noise ratio available to the receiver electronics.

Thus, there is a need for improved efficiency and a higher signal-to-noise ratio antenna that does not saturate at high frequencies, and it is to these ends that the present invention is directed.

SUMMARY OF THE INVENTION

The invention provides an antenna for a radio receiver that has high efficiency, high signal-to-noise ratio and that does not saturate at high frequencies. This is accomplished by an antenna structure which employs a ferrite core having two (or more) coils coupled together and located on the ferrite core such that the magnetic fields coupled to the coils induce signals which combine to produce a resulting signal level equivalent to the combined signals in the coils. The coils may be coupled through a transformer where the combined signals of the coils are received in the

primary of the transformer. The transformer coupling the antenna coils can dramatically narrow the bandwidth of the received signal. In addition, the antenna coils and the transformer windings may be connected to a capacitor to form a resonant circuit. The capacitor may be variable so the resonant frequency of the antenna may be set by tuning the capacitor. This results in an increased signal level and reduced interference and noise.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 shows a conventional ferrite core antenna of the prior art;

FIG. 2 shows a ferrite rod antenna with a pair of coils coupled through a tuning capacitor, and the coils being 180 degrees out of phase;

FIG. 3 shows a representation of the signals at the outputs of the windings of the antenna shown in FIG. 2;

FIG. 4 shows an embodiment of a ferrite rod antenna of the invention having a pair of coils, coupled through a variable tuning capacitor and a transformer, where the tuning capacitor and the transformer are electrically in parallel;

FIG. 5 shows a representation of the signals at the output of the transformer of the antenna shown in FIG. 4;

FIG. 6 is a block diagram of another embodiment of an antenna of the invention, the figure showing the antenna coupled to associated electronics; and

FIG. 7 is a circuit diagram of the antenna of FIG. 6.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The invention is particularly applicable to antennas used with conventional radio receivers for use in low frequency (LF), mid-wave (MW) frequency, and high frequency (HF) bands, and will be described in that context. By proper selection of materials and components, the invention may also be used with radio receivers operating at VHF and UHF frequencies. It will be appreciated, however, that these uses are illustrative of only one utility of the invention.

FIG. 1 illustrated a conventional known ferrite rod antenna 1 such as may be used in a conventional AM broadcast band radio receiver. As shown, the antenna may comprise an elongated ferrite rod 3 which has an RF tuning coil 7 wound about one end of the rod. A second pick-up coil 5 may be wound around the rod adjacent to the RF tuning coil. One end of the pick-up coil may be grounded as shown at 13. The other end 9 of the pick-up coil provides the output signal. The RF tuning coil may be connected in parallel with a tuning capacitor 11 to form a resonant circuit which may be tuned to desired frequencies of interest. In operation, the ferrite rod concentrates the magnetic field inside of the tuning coil 7 at the frequency to which the resonant circuit is tuned. The energy in the RF tuning coil is coupled by transformer action and sympathetic resonance to pick-up coil 5 which outputs the signal at 9 to the radio receiver. As described previously, since the antenna 1 uses only one pick-up coil and only one-half of the ferrite rod, it exhibits low efficiency and low signal-to-noise ratio.

In contrast, the invention provides a multiple coil ferrite antenna that provides high efficiency and high signal-to-noise ratio. As a result, it affords substantially better radio reception than conventional ferrite rod antennas of the type illustrated in FIG. 1. As will be explained in more

detail below, the invention employs two or more spaced coils on a ferrite core. Magnetic fields inside of the ferrite core induce signals in the spaced coils. The coils are coupled to a combiner which combines the signals additively from the spaced coils to provide a significantly higher signal level to the radio receiver. Preferably, was will be described below, the combiner comprises a transformer with the primary of the transformer connected to the spaced coils. The coils may also be connected to a variable capacitor to form a tuned resonant circuit, with the frequency of resonance determined by the combined inductance of the coils and the transformer. Each coil is used for both tuning and for pick-up. The signals from each coil are opposite in phase but are combined additively in the primary of the transformer to result in a significantly higher received RF signal. Tuning the antenna by means of the variable capacitor significantly enhances signal-to-noise ratio since it reduces the effective bandwidth of the antenna to discriminate against interfering signals and reduce the noise coupled to the receiver.

FIGS. 2 and 3 show a ferrite rod antenna, 21, having two spaced coils, 27, 28 wound about a ferrite rod 23 adjacent opposite ends of the rod, and connected to a variable tuning capacitor 31. One coil 27 receives 0-180 degrees of the incoming signal, e.g., an unmodulated sine wave, and the other coil 28 receives 180-0 degrees of the incoming signal. Thus, the signals on terminals A and B from coils 27 and 28 are inverted and out of phase as shown in FIG. 3, where the combined waveforms from terminals A and B have a resultant of 0 volts peak-to-peak. Thus, in the arrangement of FIG. 2, the signals effectively cancel themselves out because the RF potential between the two coils becomes zero volts when the signals are combined, i.e., the signals subtract as indicated in the view of the waveforms in FIG. 3.

By way of contrast and comparison, in a twin coil antenna according to the invention, the signals are combined so as to be additive. This is shown in FIGS. 4 and 5 where the signals from the coils 27, 28 are combined through the primary of a transformer 33. As an example, coils, 27 and 28, may be 40 turns of 12 strand Litz wire, 12 mm diameter, inserted over the ends of the ferrite rod. The winding rotation is in the same direction on both coils, i.e., coil 27 has right hand rotation and coil 28 has right hand rotation on the windings. The total inductance (L1) of the circuit of FIG. 4 is the totals inductance of coils 27 and 28 and the transformer 33. The antenna 21 of FIG. 4 is resonant at the frequency set by the total inductance and the capacitance (C) of tuning capacitor 31. These elements form an LC resonant circuit. The invention produces a significant increase in signal strength over a conventional ferrite antenna.

The secondary of transformer 33 serves two purposes. First, it is the signal pick-up coil for the transformer 33, and, second, it also limits the output bandwidth of the signal. Varying the inductance of the secondary winding of transformer will correspondingly make the output signal bandwidth greater or narrower. A narrower bandwidth increases the amplitude, reduces the noise and interference, and results in greater signal to noise ratio and more overall gain at the frequency to which the antenna is tuned.

The type of ferrite used will vary depending on the operating frequency desired. There are many types of ferrite available, as is well known to those skilled in the art, and one may be selected that has the best saturation and permeability in the operating frequency range of interest. By proper selection of the ferrite material to saturate at VHF and UHF frequencies, and by matching the inductances, ferrite material and coupling transformer, the antenna of the invention may also be used at VHF and UHF frequencies.

The antenna of the invention can be incorporated into any receiver that uses or is designed for use with a conventional ferrite rod antenna, e.g., for reception of any LW, MW, HF, VHF and UHF frequency band signals. Also, from the foregoing, it will be recognized that additional refinements can be made in the antenna to enable it to be used for other frequencies, since the operating frequency bandwidth can easily be manipulated by adjusting the inductance of the secondary transformer 33. The antenna can be used easily as a replacement unit to improve reception on any conventional radio receiver that has LW, MW, HF, VHF and UHF frequency bands, and also has applications for other frequencies.

A ferrite core antenna according to a preferred embodiment of the invention is shown in FIGS. 6 and 7. FIG. 6 is a functional block diagram of the antenna and associated electronics, and FIG. 7 is a more detailed circuit diagram of an example of the antenna of FIG. 6. For purposes of illustration, the circuit is shown disposed on two boards, an Antenna board and a Control board connected by a cable 50. It will be appreciated, however, that a single board may also be used. The illustrated embodiment in FIGS. 6 and 7 is intended for the MW broadcast band, but it will be appreciated that the principles may be readily extended to other frequency bands.

As shown in the FIGURES, the signal from transformer 33 may be fed into a J-FET push/pull amplifier 136, comprising transistors Q1 and Q2, resistors R3 and R4, and hot carrier diodes D1 and D2, for linear amplification of the signal. Hot carrier diodes are preferably used on the drains of the FETs for an ultra-quick discharge of the capacitor C2 connecting the drains of Q1 and Q2. There results a noticeable improvement in bandwidth and improved AM amplification when the hot carrier diodes were used. The outputs from the sources of transistors Q1, Q2 of the push-pull amplifier 136 are supplied to a transformer T2. Transformer T2 is preferably a center tapped transformer that feeds voltage from a power supply to the sources of the J-FETs. The signal is amplified and the combined output of the amplifiers can be seen on the secondary of Transformer T2.

The output of transformer T2 is sent through a capacitor 43 and then to transistor Q3 which is used as a buffer amplifier to drive low impedance applications. The emitter 46 of transistor Q3 goes through a filter 47 comprising an inductor L3 and capacitor C6 to eliminate low frequency oscillations. The collector 45 output of transistor Q3 goes through a capacitor 48 for decoupling and to a 330-ohm resistor 49 for impedance matching and to eliminate feedback in a cable 50 connected to a jack J1. The signal from transistor Q3 and capacitor 48 is the combined output signals from coils 27 and 28.

The output signal from Q3 is driven through the cable 50 and may be terminated in a toroid transformer 131 on the control board. The output of this toroid transformer is matched to drive the front-end of the receiver directly or it may be inductively coupled to a receiver's existing ferrite antenna using a plug-in ferrite bar antenna.

The antenna is tuned electronically with a voltage controlled variable capacitance varactor diode D3 through a network of components that keep the tuning voltage stable and accurate even in the presence of a varying DC power supply voltage and induced RF through the connecting cable. The reference voltage for the tuning may be taken from a transistor Q4, which serves as a 5-volt regulator. The regulated 5 volts from Q4 may be fed through a 56 k ohms 51 which is in series with variable resistors 121 and 122 on the control board, and to the in put of an operational amplifier 52. Variable resistors 121 and 122, may have values of 100 k ohms and 5 k ohms, respectively, serve as manual coarse and fine tuning controls for the varactor diode D3, and act together with resistor 51 as a very stable voltage divider. The output of the voltage divider is directly fed into the operational amplifier's non-inverting (+) input. Resistors 61 and 62 form another voltage divider and give feedback to the inverting (−) input of amplifier 52 to allow greater voltage range that is fully regulated at the output. A resistor 63 is a load resistor on the output of the amplifier for stability. This output voltage is fed into a low frequency RF filter comprising a capacitor 72, inductor 74 and capacitor 73. The voltage to the cathode of varactor diode D3 may be supplied through a resistor 64 (100 k ohms) and capacitor 74. The anode of the varactor is directly coupled to winding 28 and ultimately to ground through transformer 33 and winding 27. As the voltage from amplifier 52 varies in response to the tuning controls 121 and 122, the capacitance of the varactor varies and tunes the resonant circuit. Using this regulated tuning method shown, the voltage input into the device can vary from, e.g., 6.5 to 12 volts, and the antenna tuning will remain exactly where the user preset the frequency.

The control board may contain few components used principally to supply voltage and user interface to the device. As noted above, the central board may be connected to the antenna board via jacks J1 and J2 and cable 50. Diode 101 may be a standard diode that protects the unit from reverse polarity voltage at jack J3. Switch S1 is a simple on/off switch. Capacitors 110, 112, and 113 and torroid transformer III are DC line filters, mainly used when the device is plugged into an external DC source via jack J3. Normally, DC power may be supplied by a battery 114. Variable resisters 121 and 122, which may be 100 k ohms and 5 k ohms potentiometers, serve as coarse and fine tuning controls for the varactor as described above. R101 is a preset resistor to keep the voltage on the varactor pre-tuned to a specific frequency. Transformer 131, which receives the output signal from Q3, and capacitor 132 are used for the termination transformer and impedance matching. This is the final stage of the device before a clean, amplified signal is delivered to the receiver via jack J4.

A preferred embodiment of the invention as described herein comprises a ferrite core antenna, characterized by two spaced windings. The two windings are connected through a combiner, for example, the primary winding

of a transformer which additionally combines the signals from the two coils
to produce an increased output signal level. Preferably, the antenna is
resonant at the frequency of interest, and the resonant frequency of the
antenna is set by a tuning capacitor.

to me
Dear Jordan;

Thank you for your inquiry. In order, to modify the Twin Coil AM Antenna to work with the HF Band, the antenna would have to be completely reengineered. Unfortunately, this is not something we have done, or have

any information regarding. If I can be of any further assistance, please
let me know.

Subject: [Shortwave-SWL-Antenna] Re: [ptsw] Magnetic Loop augmentation
To: Shortwave-SWL-Antenna@yahoogroups.com

~15 years ago, when Lowe had gone under, I bought the last new HF-150 receiver and matching PR-150 preselector I could find from EEB in VA. I still had my much modified NRD-525 and R8, I just needed a new 'toy' to kick re-start my hobby - and it did. A few years passed and my local powerline QRM had gotten worse - I bought a Pixel, now DX Eng, RF Pro-1a mag loop antenna (... and a then new model Palstar R30a...), which became indispensable, especially when I moved to my garden home 3+ years back - with it's no outside antennas edict and HOA. I put the loop on a tripod base in the attic - and now enjoy LW, MW, & SW listening again. Of course, first I had to put the PR-150, with it's dual tuned circuits, to limit what frequency range I fed into some receivers, namely, the Lowe HF-150 and Palstar R30a.

The problem isn't in the antenna - it's produced in the receiver's front end by strong local stations mixing and cross-modulating weaker stations. It can be lessened - or eliminated - by passing the loop antenna's wideband signal hodge podge thru a frequency selective pass filter, like a real preselector. The now pricey and rare PR-150 is a dual tuned circuit such preselector which covers 100 kHz - 30 MHz in seven bands and includes the options of a wideband bypass, a built-in crunchproof CATV type follow-up amplifier, and a 10 dB attenuator. With it peaked, even on LW, CM products are gone. Some receivers just need a 6 dB drop to elimiate the production of CM/IM products, perhaps explaining whey the RF Pro-1a came with in-line 6dB attenuators.

A traditional antenna tuner is a network for matching a transmission line to a complex impedance. While it is frequency sensitive, it pales in comparison to a real preselector at lowering the level of strong off-frequency local signals. Yes, a preselector can be most useful between an amplified wideband magnetic loop antenna and a receiver.

From: chrism1111@...
Topic: 11549 Message: 11613

Apparently Litz wire if affordable, is better. Be sure you know the quality of it. Speaker wire is no different then single strand , electrically, but is more curvable. Litz wire is a series of individual insulated wires, twisted in a precise number of twists to the inch, I believe 12 twists to the inch is what is valued most. And a maker might bundle say 11 wires to a bundle then twist 10 bundles making it 110 strands. Now you have to solder all of them at each end and avoid taps. So if you make coils for your set make a coil for each band you want to cover.

this web site may help.

http://www.makearadio.com http://www.makearadio.com/crystal/16.php

Please not the owner of it does not answer emails or questions. So many people use ad blocking software it stops him from making a buck or two. His knowledge bas is quite large and his projects are many, including antenni I remeber being called a Crystal Kludge, in a book from the now extinct Lindsy's Publications!

He apparently had a how to on making a wire twister to make Litz wire. I could not find it. Basically it must be a version of a twine/rope making machine.

I doubt I helped but maybe I did. Others will have and better things to add I am sure. good luck

Hi

What you are looking for is maximum surface area to build lowest inductance loop(s).

Litz comes in several gagues each size up giving more strands of wire.

Speaker cord is significantly different and better than single strand at Radio Frequencies.

Flex Weave Multi Strand Antenna Wire is better than Speaker wire or household ZIP cord.

11616. Re: [loopantennas] Re: Loop Material

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-11 02:59:19 UTC
From: BobC
Topic: 11549 Message: 11616

Litz wire is primarily used to lower the resistance of a conductor to the flow of ac current. This resistance is caused by limitation of current flow to the area near the conductor's outer surface; this resistance increases with frequency. By dividing a conductor into multiple, insulated strands, the surface area for the same diameter wire is effectively increased, thus lowering its RF resistance. According to the literature, the effectiveness of Litz wire drops off significantly between 1 MHz and 2 MHz. It was used extensively in air-core loop antennas for AM tube radios and may still be found in some ferrite loop sticks.

I have used Litz wire on occasion, mainly adapting old radio coils to portable loops, but never found them to be significantly better. My longwave loop is 3-ft square (51-in dia.), consists of 80 turns wound in a single plane pancake style using AWG 22 stranded wire. Length of the wire is in the hundreds of feet. Still, it produces a very high Q, i.e., low resistance at resonance, resulting in a bandwidth so narrow that it must be repeaked every 1 kHz. While they last, some high-powered trans-Atlantic broadcast stations still make it across the pond and can be sniffed out with this antenna.

11618. Ferrite mix for antenna bars at higher frequency's

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-13 13:26:33 UTC
From: kthkit@...
Topic: 11618 Message: 11618

Hi all,
I found some ferrite antenna bars type F28 from NEOSID/MMG and the data sheet specification.
I think it is used for old type PAGER receivers working on the mid range VHF frequency + -70 MHz.
The initial ferrite los is low and the initial permeability is 30.
Have any one experience with this ferrite mix as antenna bar for shortwave receivers ?

See data sheet in the files.

From: n7chs@...
Topic: 11622 Message: 11622

I have committed myself to building a small loop antenna. I have acquired a variable vacuum capacitor and now I am looking for the radiating element. Your assistance is appreciated in narrowing down my choices in:

Loop Material
1 inch copper pipe 7/8 inch helical coax Number of Loops
One loop 8 feet in diameter Two loops 3 - 4 feet in diameter With this arrangement I would use one length of coax to form two loops
I have no desire to recreate the wheel so I look to your thoughts or suggestions.
Thanks,
Chuck N7CHS

Hi

The name of the game is maximum surface area. RF propagates on the surface of a wire/conductor.

If your metal working skills are up to it consider rectangular ribbon/bar stock. Look at a Fractal Loop.

I would recommend a single loop as another rule of thumb is Maximum Area. A second loop will add to the distributed capacitance lowering the maximum resonant frequency.

Wire/conductor length roughly 1/20th wavelength.

Date: 2016-11-15 19:14:05 UTC
From: Ray, W4BYG
Topic: 11622 Message: 11625

Chuck,
You don't mention what frequencies you wish to cover. Also, I don't believe you'll see much difference between the 1" copper pipe and the 7/8" Heliax, (other than the copper pipe will be much heavier to deal with).

Generally I would keep a transmitting loop slightly less than 1/4 wavelength circumference at the highest frequency you are planning for. This gives very good efficiency at that frequency and reasonable efficiency the next band down.

My 20 meter loop has about .2 wavelength circumference of 1.5" copper strap mounted on a PVC frame and is tuned by a 50pf vacuum cap. It is narrow band as expected, but works surprisingly well on 20.

I have no experience with a double loop.
73,
Ray, W4BYG

The Fractal Antenna was a great suggestion. I should have included in my original post: Have an inexpensive source for 1 inch copper pipe and 7/8 inch helical coax. Preferred bands to operate, 80 - 20 meters. The Loop calculator is also much appreciated. Is anyone aware of a web based calculator that includes two loops for radiators?

Thanks,
Chuck
N7CHS

11631. RE: [loopantennas] Dual Magnetic Loop Antenna / Fractal loop nonsense

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-17 01:00:50 UTC
From: Leigh Turner
Topic: 11622 Message: 11631

I have to laugh out loud when I see misguided designs and TMLA constructions like this! Fractal nonsense and BS! Caveat Emptor....Crazy Daisy alright; its plain loopy :-)

Concertinaing the loop radiating element like that does nothing/little to contribute to the antenna□s critically important Radiation Resistance. That key parameter is loop enclosed area based. Folding the lineal perimeter length of the loop element merely shrink compacts the antenna size by introducing additional loop inductance / XL reactance. It only allows a structural resonance to be achieved in a smaller diameter loop with a practical / convenient value tuning capacitor.

There are no free lunches here, and attempting to violate the underlying electrically-small loop antenna physics is a fruitless exercise and tantamount to folly. It will work on Rx OK, but will be a relatively wet noodle on Tx (compared to the radiated field strength achievable from a properly / optimally designed small magnetic loop antenna.

Cheers,

Leigh
VK5KLT

Subject: Re: [loopantennas] Dual Magnetic Loop Antenna

Posted by: n7chs@...

The Fractal Antenna was a great suggestion. I should have included in my original post:

1. Have an inexpensive source for 1 inch copper pipe and 7/8 inch helical coax.
2. Preferred bands to operate, 80 - 20 meters.
The Loop calculator is also much appreciated. Is anyone aware of a web based calculator that includes two loops for radiators?

Thanks,
Chuck
N7CHS

Hi
I have been doing research for a HF SWL Receive Only loops and that is where the Fractal Loop came in to get longer wire length in a single turn. However Fractal/wire-length is only one factor in the complexity and compromise of loop designs as pointed out elsewhere in this Topic. Also your pragmatic limitation(s) of cost of material(s) puts paid to a Fractal design.

However you need to elaborate on your two coils inquiry. What are you trying to accomplish?
Two turns spiral wrap?
Two coils side by side?
Two coils one above the other?
Two coils not in the same Plane?

When push comes to shove follow the lead of the popular successful commercial Antennas no need in reinventing the wheel.

Flat 6 cond. Telephone cable. 2 fiberglass rods from harbor freight. Makes a nice 6 turn loop. Ferrite core on one cond for coupling to coax

Hi
Further towards the loop material.
The corrugation gives a slightly longer length along the surface (equal diameters), theoretically speaking. However bottom line is lowest inductance/maximum surface area.

11635. Pixel RF PRO - 1B information

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-11-20 00:56:05 UTC
From: n40cla@...
Topic: 11635 Message: 11635

What I am curious about in the RF PRO-1B antenna is what is inside the electrical box on the bottom of the loop itself. The reason I am interested is that I have built an octoloop for the VLF/LF range 50kHz to 500kHz. I receintly came across the bottom half of the RF PRO-1B and am curious as to how they are interfacing a piece of RG6 from the preamp to the bottom of the antenna. I thought there had to be some sort of hi impedance to low impedance transformer between the antenna and the coax. If someone has a the ability to make a photo of the inside of that box and email it to me I would appreciate it.

Thanks
Fred N4CLA

Hi Fred,

I checked mine out some years back when I first got the loop and had some intermittent problems with the loop. The box contains a 1:1 RF transformer: Mini Circuits Lab (MCL) T1-6T transformer with the center-tapped winding on the loop side and center tap to common/ground. http://www.minicircuits.com/pdfs/T1-6T-KK81.pdf

The output side (non-centertapped) has a series isolation 1 uF (plus 0.1 uF cap in parallel) cap to the output coax center connector. That's all there is, and these components are on a small PCB. (Note the loop is a "moebius" loop, thus has two turns with the connections at the top of the loop criss-crossed.)

(The RF preamp box is a 50 ohm in/out preamp with about +30 dB gain and a low noise figure--designed by Jack Smith K8ZOA (SK) who used to run Clifton Laboratories.)

(And sorry, no actual photo of the PCB/box contents.)

73,

Steve AA7U

Hi, a quick question about this loop if you don't mind me jumping in. I'm looking for a good receive antenna. How does the pixel loop pro-1b compare to the similiar wellbrook loop 1530?? Also does height matter in its placement? I have a 50 ft crank up tower I could Place the loop on, would it help vs. placing the loop At ground level? Thanks for a great thread. John

Hi John,

At the time I had both a Wellbrook 1530 and the Pixel loop and had them set up same height (about 6' off the ground) and near each other. They generally performed about the same. Wellbrook has a better model out now with a low noise amp (LNA model) which I would give the nod to over the Pixel (now sold by DXE).

Untuned broadband loops such as these do not need to be raised off the ground; they'll even work placed right on the ground if that's the only mounting option. Much more important is to get the loop away from anything nearby with AC power, especially if LF reception is desired. Of course if you have metal buildings nearby or homes (with all the modern RFI noise) then getting the loop away from all that would help, and might mean putting the loop higher to get out of the AC noise field.

73,

Steve

Good morning Steve,

When you say 0.1 microfarad inparallel do you mean that the 0.1 microfarad cap is connected between the braid of the coax and the transformer??

Morning Steve,

Thanks for you quick reply. So the two capacitors are just in parallel with each other and both connect the same side of the transformer to the center of the coax?
I really wonder why or what this might bring to the table?

Jef

I bought one of these for evaluation. An ordinary
10 foot circumference loop is 1/3 wavelength at
30 MHz. It goes resonant at 1/2 wavelength. That
is the basic concept of the Wellbrook loop, etc.
If the loop is "shielded" and has a dielectric
other than air, the loop may reach resonance before
it gets to 30 MHz. At resonance, there is a suck
out in response.

The Pixel loop has essentially two turns. This reduces
the half wave resonance to around 10 or 15 MHz including
the effect of the dielectric. On a network analyzer,
the impedance circles around the Smith chart as expected.
IMHO, regardless of the original top secret EMP design
(it might have been good for EMP) this makes no sense.
The loop does still work after a fashion in spite of this.

They ship a very nice Clifton Labs preamp in a weatherproof
box with it. This is the best part. I use the preamp with other
antennas I am experimenting with. The loop sits mainly unused.

I have had a Pixel RF PRO - 1B since 2012. It's an excellent performer and a great addition the antenna farm. But it doesn't replace everything else.

For example, compared to my active whip it ran out of gas in the lower third of the MW BCB.

I mentioned this to Pixel and they provided an outboard preamplifier that brought the loop to parity with my active whip antenna. Very much appreciated that as I wanted to use the loop in the MW BCB for both its lower noise pick-up property, and it's directional nature.

But even with the outboard preamp below about 250 Kc's it once again runs out of gas. The active whip far outperforms it below that frequency. It's advertised as usable to 50 Kc's but I find that highly unrealistic.

Mechanically it has been very sound, surviving an 80 mile-per-hour wind in 2015.

I temporarily mounted mine on a tripod and tested it in several locations around my yard and on the roof of my house. It ended up going on a gable end of the roof because of better signal strength and less noise pickup.

So my experience after 4 years is it is my go-to antenna for everything from the NDB band, upward.

If you want to listen to LWBC or any of the military VLF utility stations or try to hear the Alpha's you'll need an active whip in addition to the loop. For BCB and SW the loop is the ticket with its comparable signal strength, and much lower noise.

Scott

I have just uploaded a drawing of the loop and output transformer to the Files. I'm guessing the isolation capacitor is to give protection for the power inserter should the user accidentally hook the coax cable back to the power inserter directly to the loop instead of to the preamp.

Steve

Hi
Since you guys know what's going in the Pixel and possibly the Wellbrook
can you explain where the resonating capacitance is?

The Pixel and Wellbrook are broadband loops, and there is no resonating capacitor. See:
https://groups.yahoo.com/neo/groups/loopantennas/conversations/messages/11401
and work from there.

hi Steve thanks for that. how would the Wellbrook or Pixel loops compare with a ferrite sleeve loop?? Obviously the Wellbrook and Pixel loops are broadbanded when it comes to tuning, but i've been reading a bit about ferrite sleeve loops and they seem pretty amazing even though you can only tune one frequency at a time. is there anyway to make a FSL broadbanded when it comes to tuning like the wellbrook or Pixel loop and have you ever built one?? One in particular i've been reading about by Gary deBouk has 108 ferrite rods. I would like to try and build sometghiung like this for LW and MW, is it worth it??

Thanks again, John

  Hi John, At the time I had both a Wellbrook 1530 and the Pixel loop and had them set up same height (about 6' off the ground) and near each other. They generally performed about the same. Wellbrook has a better model out now with a low noise amp (LNA model) which I would give the nod to over the Pixel (now sold by DXE). Untuned broadband loops such as these do not need to be raised off the ground; they'll even work placed right on the ground if that's the only mounting option. Much more important is to get the loop away from anything nearby with AC power, especially if LF reception is desired. Of course if you have metal buildings nearby or homes (with all the modern RFI noise) then getting the loop away from all that would help, and might mean putting the loop higher to get out of the AC noise field. 73, Steve

Hi
Two questions.

Is there such a thing as a Ferrite HF/SWL Antenna?

How would a Pixel and Wellbrook fare against a Varactor tuned Loop, one turn, 4 foot diameter HF/SWL Loop?

I have been able to tune up a little over 10 MHz with a Ferrite Loop after that capacitance limits the top end.

John,

A none resonant FSL may have a a reasonable impedance match to the Wellbrook Flag amplifier; the FLG100LN (Serial No. 200 onwards) which has an approx. 800 Ohm input z. However, the input matching transformer may degrade the amp. NF of 0.11dB to approx. 0.3dB. Its hard to say whether the sensitivity of the broadband FSL would be as good and the tuned version.

Topic: 11635 Message: 11658
Attachments: 3 described; binary payloads are missing from this source WARC

Andrew,

It is stated that " the FLG100LN uses 4 JFETS in parallel push pull, cascode with optimum noise-less transformer feed back". While I understand (or at least I think I do) every word of this sentence I still have trouble to understand the concept. A push pull requires two Jfets and a push pull cascode requires another two Jfets which is a total of four. If you use parallel Jfets the total would go up to six or even eight Jfets…. So what I am missing here? I do understand the concept of noise-less feedback. Are you willing to enlighten us a bit on this issue?

Best regards,

Jef

Subject: Re: [loopantennas] Pixel RF PRO - 1B information

hi Steve thanks for that. how would the Wellbrook or Pixel loops compare with a ferrite sleeve loop?? Obviously the Wellbrook and Pixel loops are broadbanded when it comes to tuning, but i've been reading a bit about ferrite sleeve loops and they seem pretty amazing even though you can only tune one frequency at a time. is there anyway to make a FSL broadbanded when it comes to tuning like the wellbrook or Pixel loop and have you ever built one?? One in particular i've been reading about by Gary deBouk has 108 ferrite rods. I would like to try and build sometghiung like this for LW and MW, is it worth it??

Thanks again, John

Hi John,
At the time I had both a Wellbrook 1530 and the Pixel loop and had them set up same height (about 6' off the ground) and near each other. They generally performed about the same. Wellbrook has a better model out now with a low noise amp (LNA model) which I would give the nod to over the Pixel (now sold by DXE).
Untuned broadband loops such as these do not need to be raised off the ground; they'll even work placed right on the ground if that's the only mounting option. Much more important is to get the loop away from anything nearby with AC power, especially if LF reception is desired. Of course if you have metal buildings nearby or homes (with all the modern RFI noise) then getting the loop away from all that would help, and might mean putting the loop higher to get out of the AC noise field.

Jef,

Each side of the push-pull amp. (ALA100LN and FLG100LN)uses 2 JFETs in parallel, The upper half of each push-pull cascode is a single 2N4401 (Now obsolete On-Semi Device). Using an On-semi device 2N4401 in this configuration as apposed to a JFET significantly reduces the IMD. Other makes of the 2N4401 are not as linear!

The ALA1530LN/P has 4 extra Jfets to increase the gain and reduce the NF to 0.07dB. Or put it another way, the amp. noise floor is 18dB lower compared to the thermal resistor noise at 290K. This low noise may appear to be an overkill, but it is still noticeable when comparing it to the ALA1530S+ with its 0.45dB NF (noise floor is 10dB lower compared to the thermal resistor noise at 290K.)

Andrew,

It is stated that " the FLG100LN uses 4 JFETS in parallel push pull, cascode with optimum noise-less transformer feed back". While I understand (or at least I think I do) every word of this sentence I still have trouble to understand the concept. A push pull requires two Jfets and a push pull cascode requires another two Jfets which is a total of four. If you use parallel Jfets the total would go up to six or even eight Jfets…. So what I am missing here? I do understand the concept of noise-less feedback. Are you willing to enlighten us a bit on this issue?

Best regards,

Jef

Subject: Re: [loopantennas] Pixel RF PRO - 1B information

John,

A none resonant FSL may have a a reasonable impedance match to the Wellbrook Flag amplifier; the FLG100LN (Serial No. 200 onwards) which has an approx. 800 Ohm input z. However, the input matching transformer may degrade the amp. NF of 0.11dB to approx. 0.3dB.

Its hard to say whether the sensitivity of the broadband FSL would be as good and the tuned version.

Good afternoon Andy,

Fully understood now and yes I really do like the 2N4401 so some years ago I did buy a full reel of them which will last me a life time….
Somewhere I still have some push pull cascode amplifiers but with single J310 on each side followed by a 2N4401. I will do some digging tonight and try them out on my attic flag antenna.

I also had very good luck with two 2N5109 transistors in a push pull configuration as emitter followers. The noise figure will be a lot worse than your concoction but it seems to work very well on small loops with a termination resistor of some 500-1000 ohms. The results are actually very impressive on the 27 and 28 mhz bands where my loop is close(r) to resonance.

Thanks again for your explanation,

Jef

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11666. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-01 14:05:23 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11666

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11667. HF Loop Hack

11668. yes, a High power loop question

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-02 03:56:17 UTC
From: kf4dcy@...
Topic: 11668 Message: 11668

Has anyone made a high power legal limit mag loop antenna? If so what voltage cap does it take. My plans are to build a big 160 meter loop and vary it with an adjustable slide plate cap with dielectric polyethylene laminated plates. And the sliders coming uncoupled about an 1/8 inch, the lamination will assure a recoupling. This so the pf will fall off to even lower pf figures. Using a rack and pinion to drive the variability. And a ho scale train transformer to vary the speed of a dc powered drill motor and reduction gearing. And a double pole double throw switch to reverse 'in' from 'out'.

From: J Ferrow
Topic: 11670 Message: 11670

Hi, How does one feed the output of a tuned loop to a radio that doesn't have a built in ferrrite stick??

also how far away can the tuning capacitor be from the tuned loop for it to work? is there any way i could place a LW loop outside and tune it with a variable air core cap at my desktop where my radio is?? Is this possible??

Thank-You, John

Hi
Will need more info to give a complete answer.

Does the Radio allow connection to an external Antenna? Does the Radio have a Whip Antenna?

Are you talking about an existing Loop Antenna? If so please describe.

Remote operation of a Loop Antenna is usually done with a Varactor Tuned Low noise amplifier, sometimes with an untuned broad band amplifier .

Take a look at the Addawards which claims to add LW that it's kissin cousins Degen & Kaito do not have.

"There is a new, re-designed antenna that was based off the TG34 (and KA33 – no longer in production). Since I wrote this Guest Post, I have ordered the ADDWARDS A38-LMS from Anon Co. in China. The A38-LMS is said to have more durable (thicker) wires than the TG34, it now has a dial to control “Gain” and the bands are now separated in three vice two (LW, MW, SW switch). Since I really like the TG34, I’m very hopeful this new A38-LMS is even better."

11672. Addaware A38-LMS Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-07 00:33:21 UTC
From: Jordan Dobrikin
Topic: 11672 Message: 11672

Hi
Does anyone have Schematics and/or know what is going on with the switch on the Antenna Module?
What is it switching, Loops or an inductor??
73 de Jordan ve7jjd

Addaware vs et.al.
From SWL Post:
"There is a new, re-designed antenna that was based off the TG34 (and KA33, no longer in production). Since I wrote this Guest Post, I have ordered the Addaware A38-LMS from Anon Co. in China. The A38-LMS is said to have more durable (thicker) wires than the TG34, it now has a dial to control “Gain” and the bands are now separated in three vice two (LW, MW, SW switch). Since I really like the TG34, I’m hopeful this new A38-LMS is even better.
The best deal is the Degen DE31MS, Kaito KA33, TG34, Kestrel W31MS. These are all the same antennas, under different name brands and models. It's an active MW/SW loop. It's a winner."

11673. HF/SWL Ferrite Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-07 01:11:36 UTC
From: Jordan Dobrikin
Topic: 11673 Message: 11673

Hi
I am seeking advice assistance and comment.
I am trying to design and build a HF/SWl Ferrite Loopstick Antenna, for use in retrofitting Radios and the C.Crane Twin Coil Antenna.
It is my understanding that I should use heavier gage wire, wound evenly spaced on a *long ferrite rod* to get low inductance with maximum surface area. Litz apparrently poops out above 2 MHz.
Plan A would have a plug connector on the loop assembly to plug into a radio's external antenna jack.
Plan B would be to open the Radio and connect the new antenna in parallel with the existing Loop antenna or to bypass the existing loop antenna.
With respect to the C.Crane a similar plan of attack; opening the Antenna Module to access the existing coil connection to the amplifier.

The unavoidable component when coupling a tuned loop to a receiver, regardless of whether it is going to a ferrite antenna core or to some other input circuit is the lead-in or transmission line. This will necessarily be low impedance - on the order of 50 to 100 ohms. So the output of the tuned loop must match this as closely as possible.

At resonance a tuned loop having the capacitor and coil in series with lead-in will produce the necessary low impedance. That would be the simplest way to solve the problem. However, with this arrangement, the lead-in now acts as a resistive load in the tuned circuit and will cause some lowering of the circuit Q, i.e., the bandwidth will be wider and gain lower.

I prefer to let the tuned circuit "freewheel" in space and use a low-impedance coil to couple the field transformer-style to the lead-in. The low-impedance pick-up coil can be just a few turns of wire mounted coaxially with the tuned circuit and connected directly to the lead-in. Again, the pick-up coil should match the impedance of the lead-in at the tuned frequency. One size pick-up coil will do the job if the frequency range of the antenna is not too great. For shortwave loops covering several MHz, it will be necessary to tap the pick-up coil to produce the proper impedance.

It is not practical to separate the variable capacitor from the coil in the tuned circuit. Remotely tuned loops generally use varactor diodes, which vary the capacitance proportionally to the reverse voltage impressed across them.

If there is any way a tuned loop can be operated in close proximity to the radio, it should be done in preference to remote tuning. It comes down to complexity and logistics of building and operating a remote loop. Building materials and noise may be impediments to indoor loops, but a well designed loop has excellent noise reduction characteristics and can sniff out microvolt signals with amazing clarity.

Bob C.

Hi
If one is handy try a Rube Goldberg solution with Radio Control Model Servo.
Also consider a Vacuum Variable Capacitor, overkill for capacitance, but
easy to rig up remote control. They are available on ebay for relatively
low cost

No, the tuning capacitor cannot be a distance from the loop. The wires connecting the loop and the variable cap would add so much capacitance in parallel with the variable that the change in C from min to max would be so low that the loop would only tune over a very narrow range.
In addition, the connecting wires become a part of the loop coil altering it's geometry and thus performance.

If you want remote tuning - I recommend using a varactor tuned loop. You have to modify the traditional loop architecture by adding a DC blocking capacitor so the loop itself doesn't short out the power going to the varactor. I have a small weatherproof box containing the varactor tuning circuit mounted on the outdoor loop. Inside the house, I have a little box that houses a 9V battery and a 20 turn potentiometer. The only thing I need to add is a way to rotate the loop outside.

11679. Longwave Loop Antenna

Hi
The Addaware is the new kid on the block adding Longwave.
73 de Jordan ve7jjd

http://www.anon-co.com/product/a38lms-antenna
http://www.anon-co.com/product/degen-de31ms-antenna

A38-LMS Addwards http://www.anon-co.com/product/a38lms-antenna
A38LMS $17.99
A38-LMS active loop antenna (LW, MW AND SW)
Description:
This “Active Loop Antenna” is able to tune and amplify the LW, MW and SW frequency band, thereby enhancing signal reception quality and increasing your overall radio listening experience. Use the “TUNING” knob to fine tune the reception signal, and attenuate the signal by adjusting the “LEVEL CONTROL” knob if there is interference caused by a signal that is too strong.
Specification:
Frequency Range:
LW: 120 ~ 400 kHz
MW: 520 ~ 1710 kHz
SW: 3.50 ~ 20.00 MHz
Power source: 2 x AAA battery (not included)
Power consumption: 8 mAh
Instructions:
1. Take out the parts and place the suction cup (7) onto the clean glass of the window.
2. Extend the wire antenna loop of the amplifier (2) by using the extension rod (6), then hang it on the hook of the suction cup or fasten it to the curtain using the clip (8).
3. Insert two batteries (AAA, UM4) into the control box (1) and close the battery cover. Place it beside your radio, plug one end of the cable (5) into the amplifier and the other end into the control box.
4. Select your desired band from the amplifier, then push the “POWER” switch of the control box to “ON” position; the power indicator LED turns green.
For SW:
If your radio has an SW antenna input jack, connect the 3.5mm plug of the control box into it; if not, then connect the 3.5mm plug of the control box into the black and red connector clips (4). Fasten the red clip to the telescopic antenna of the radio and the black clip to a self-made grounding line.
For LW/MW:

If your radio has an MW antenna input jack, connect the 3.5mm plug of the control box into it; if not, then connect the 3.5mm plug of the control box to the ferrite bar antenna coupler (3) and place it near the built-in MW antenna of the radio. For pocket sized radios, you can use the base station (9) to keep the ferrite bar antenna coupler near the MW antenna.
5. Dial the “TUNING” knob of the control box up/down for better signal reception.
6. Dial the “LEVEL CONTROL“ knob of the control box up/down if the radio signal is too strong and causes a distorted sound.
Included items:
1. Control box
2. Amplifier
3. Ferrite bar antenna coupler (for LW/MW)
4. Black and red connector clips
5. Cable with 3.5mm plugs
6. Loop extension rod for wire antenna
7. Suction cup
8. Hanging clip
9. Base station: for pocket radio

DEGEN DE31MS http://www.anon-co.com/product/degen-de31ms-antenna
DE31MS $13.99
DETAILS
Description:
The DE31MS is an active loop antenna for MW & SW reception. This antenna is specially designed for world receivers for enhancing signal reception. The small size and light weight is perfect for carrying around, traveling or simply for use at home and in the office.
Specification:
Frequency Range:
MW: 531 ~ 1602 kHz
SW: 3.90 ~ 22.00 MHz
Power source: 2 x AAA battery
Power consumption: 6 mAh
Operation:
1. Take out the unit and place the suction cup onto the clean glass of the window.
2. Drag all the soft antenna loops of the telescopic antenna, hang it onto the hook of the suction cup or fasten it to the curtain using the clips.
3. Insert two batteries (AAA size) into the controlling box and close the lid of the battery compartment. Put it beside the radio. Plug one end of the connecting cable into the amplifier box and the other end into the controlling box.
4. If the radio has the antenna input socket, plug the output port of the controlling box into the antenna input socket of the radio. Otherwise, plug it into the socket of the connector. Fasten the white clip of the connector to the telescopic antenna of the radio and fasten the black clip to the grounding line (connecting grounding line is very good for receiving

signals) of the radio.
5. After connecting correctly, turn on the power of the controlling box. The power indicator of the controlling box is bright.

How about an enclosed flexible cable, coupled to the cap on one end with knob on the radio end.....like the old speedometer cables. ?????

Too crude perhaps?

John.....IL

Subject: Re: [loopantennas] how to feed the output of a tuned loop to a receiver?

No, the tuning capacitor cannot be a distance from the loop. The wires
connecting the loop and the variable cap would add so much capacitance
in parallel with the variable that the change in C from min to max would
be so low that the loop would only tune over a very narrow range.
In addition, the connecting wires become a part of the loop coil
altering it's geometry and thus performance.

John

The problem with this arrangement is that the tuning will be very imprecise and subject to sudden motion due to the cable binding within the armoring. Fine tuning ability is not a characteristic of this method.

Well, if you can find a REALLY long cable :)

Varactor capacitor tuning is the easiest method, but may have intermod problems with a really strong local signal. Motor control of a air variable cap with a large reduction gear between the motor and the cap works well.

There is one part on the schematic that I can not find. I would like to know what the specifics are for Siemens Ferrite Ring-core P/N B64290K618X830. It appears that P/N is no longer manufactured as well as the web site www.electrovalue.co.uk (http://www.electrovalue.co.uk) that is supposed to be the source does not exist. Is there anyone that can find the specifics for that core so I can find another substitute? I have sent Graham several emails to the email address on the schematic and have not heard back from any of them. Maybe he has a new email address that someone can share.

John, this looks like a very nice preamp that could be made to work on many loops.

Thanks

Fred - N4CLA

Hi Fred Thanks for getting back, I'll play around with different cores and see if it makes much of a difference if I can't find it. I do have a few questions about construction. it says a 6X6 square loop, does that mean each side of the square is 6ft long?? Also it points to a center tap to the wire. the wire is specified to be 6 turns around that loop, so the center of the wire, that would be the 3 turn point. is where the tap goes??
Thanks, john

Greetings, Jordan, from Max , Amongst the clutter at this computer are two antennas made from ferrite rods. The rods are nine inch by about three eights, type unknown. One consists of two rods butted together using a dab of super glue. The joint was left to cure for a few days then reinforced with a sheet of note paper and araldite wrapped around. Enameled wire 0.5mm dia. was wound on to make a coil about four inches long. The device tunes from 320kHz to 570kHz using a MFJ-936b loop tuner. It posses the atributes you would expect from a ferrite loop antenna. By using less wire and and a different position of the coil on the ferrite HF and SW reception could be achieved.
The second antenna consists of 30inches of 16mm pvc pipe. Each end of the pipe has a nine inch ferrite rod secured inside. A coil of wire is wound, at each end, over the outside of the pipe. Each coil is wound in the same "sense". The inboard ends of each coil are joined together. The outboard ends or the coils are connected to the MFJ-936b. Each coil here is about 35 turns of hook up wire. The antenna tunes1.2MHz to 2.0MHz. The null is very sharp and seems almost bottomless, noise goes into it and is never heard again Hi Hi. Please excuse any typos, its been a long day at 37DegC another like it tomorrow.
A bushfire is burning to the west, a large column blue grey smoke can be seen, usual for this time of the year. Regards to all VK2TTI

Hi
To all my followers and acquaintences.

Low Self Discharge Batteries for SWL Radios, RC Sail Boats, and general Household uses.

With AA &,AAA with AA to D and AAA to C Battery Adapters.

Rechargeable Alkaline and Low Self Discharge NIMH Batteries (ENELOOP, et. al.).

Rechargeable Alkaline are lower cost and fit a niche market of applications that do not need high power surge loads that NIMH can Supply. Portable Radios Flash lights, TV/Stereo Remote Controls. Also they rate 1.56 volts as opposed the 1.20 volts of NIMH.

Now on to Low Self Discharge NIMH. Note that the Enloop Panasonic Chargers are a better bet for the Average User;IMHO.

NiMH Battery Roundup - Eneloop, EBL, Sunlabz, Amazon, and Other AA Cells Tested
S.co.tt 2,562 1,404 views Published on Sep 22, 2016
It's not every brand or type of AA NiMH cell on the market, but it's a bunch of the popular ones. Also some really, really crappy ones. If you're trying to figure out which cells to buy, this is the video for you.
I also get extensively into the testing methodology, so if you're interested in doing your own comparison this may prove helpful. But don't worry, I go full spoiler and give you the results right up front.
https://www.youtube.com/watch?v=846m-boWB64&t=71s

---

http://www.ebay.com/itm/Panasonic-Ni-MH-Charger-BQ-CC17-for-AA-AAA-Batteries-/151549081302

- 4 Position Ni-MH battery charger delivers advanced, individual cell charging capabilities.
- Ideal for use at home, in the office, or on the road.
- retractable AC Plug makes storage or travel convenient.
- Individual Battery Charging - charge any combination of up to four AA or AAA Ni-MH rechargeable batteries.
- Auto Shut-Off safety technology - automatically stops if a non-rechargeable battery is inserted into the unit or charging process is complete.
- Individual LED Charging Indicators - Lights turn on during charging process and turn off when the specific battery cell is completely charged. there is one LED light for each battery cell.
- ---
---

http://www.ebay.com/itm/Panasonic-eneloop-Pro-Charger-BQ-CC55-Quick-smart-individual-charger-4-bay-AA-AA-/201748235722

*Brand New **Sealed in Shrink for internet sales no retail packaging*

Panasonic eneloop Pro Charger BQ CC55 Quick smart individual charger 4 bay AA/AA

need 8 or 12 or a 16 bay charger buy a bunch of these

New for Fall 2016. The long anticipated upgrade to the best rated eneloop "Advance" charger model BQ-CC17 is here. The eneloop "Quick" charger is the highest performing safest automatic charger Panasonic has ever offered. Put 4 batteries in and BAM 1-4 hours later your fully depleted high capacity AA or AAA batteries are charged to perfection. No Programs to set no buttons to push just set it and forget it. Each battery is fully charged every time and never overcharged. Get the most out of your batteries with this charger your batteries will last and last while providing optimum performance. Recommended for family's and children 8 and older. You simply can't go wrong....if you do not agree PLEASE RETURN THIS AT MY EXPENSE you have 60 days.

Recommended for High Quality NiMH LSD batteries like: eneloop, Fujitsu, Imedian, Amazon basics, Energizer, Duracell etc.

This advanced AC charger is designed to charge battery cells individually; allowing you the freedom to completely charge fully discharged cells or just "top off" the charge of AA or AAA cells that are only partially drained. The single cell charge capability allows any combination of one, two, three or four AA or AAA Ni-MH batteries to be charged at the same time.

To: Shortwave-SWL-Antenna@yahoogroups.com

I find that some of the smart chargers I have, will not charge or recognize
some batteries. I also find that the old "dumb" Energizer charger I have
had for 8+ years, will fully charge any rechargeable AA or AAA I have. It
may not be as quick, but it never fails. The only issue I have with it is
the batteries must be paired together. They cannot be individually
charged. Now I know that may not be optimal, but it is much much better
than not being able to charge them at all. And after I get them near full
charge, I can switch them over to an enelope type charger for finishing. 73

Hi

The ultimate Stealth Antenna!!!
How many Housing Associations regulate against Lawn /Patio or Balcony Furniture?
I am going to use with a HF/SWL, Receive Only, Remotely Tuned, Magnetic Loop Antenna. Ultralights use it for a portable Field Day Antenna
You HAMS use something robust but flexible, like FlexWeave.

11702. winding a toroid.

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-20 02:13:01 UTC
From: J Ferrow
Topic: 11702 Message: 11702

Hi, can someone share with me their method of winding a toroid? specifically it's the transformer in Graham Maynards active loop circuit. the specs call for 8 windings - center tap - 8 windings on the primary and then an 8 winding secondary.
my question is regarding the center tapped primary. Do i wind 16 turns on the primary then just tap it in the middle with a length of wire soldered to approx. the eighth turn (the middle) or can i wrap eight turns use the "end wire" of those turns as the center tap, then wind another eight turns, but use the "beginning wire" as the center tap. In other words I would have two wires as the center tap, but i would have a total of 16 turns.

Thanks to all, John

11703. Re: [loopantennas] winding a toroid.

Hi,

Normally you wind 8 turns. Make a loop in wire, twist it tightish, then continue with the rest of the wire for other 8 turns. The twist is then shortened to suit and soldered together and is your center tap.

Cheers,
Will

John
As the windings are all 8 turn multiples you can twist three wires together then wind eight turns
through the core, joining one start to another finish to make the 8+8 center tapped winding. Twisting the wires together increases the coupling between the windings and helps ensure good balance and a wider and flatter frequency response

To make things simpler you can color two wires with different spirit marker pens before twisting so that it is easy to connect them after winding the core. Something around 5-8 twists/ inch will be fine but not at all critical for this use. You count turns as the number of times the wire passes through the hole.

A great source of cores and info is www.kitsandparts.com. There is a very handy page of info for every core they sell with a handy calculator for inductance/ frequency/ capacitance/ turns and wire length- you put in what you know and it tells you what you did not know.

Jordan,
I never found ferrite loops to be very effective for shortwave reception. You can get marginal performance up in the the tropical bands, Stick to a longwire or skywire loop for good DX. Sorry for the late reply.

OK try again!

The primary is 8 turns + 8 turns, the secondary is 8 turns. So we wind 8 turns on with three wires,
Lets call them red green and blue. You connect the start of the red to one of the junctions of two (upper)220 ohm resistors, the end of the red then joins the start of the green, that junction going to ground. The end of the green is the other junction of the (lower) 220 ohm resistors. The blue winding is the secondary and the output to the receiver.

So one half of the primary is the red winding of 8 turns, the other half is the green winding of 8 turns. The end to start connection puts the centre tap (of the total 16 turns) in the exact centre electrically. The circuit has two three transistor amplifiers, the top amplifier produces an output of reverse polarity to the lower amplifier so the two primary windings are connected start to finish to correctly add the two signals together.

Winding the three wires together is much better electrically than winding three separate coils, the twisted wires produce much better coupling and balance between the windings. You space the turns so that the start and end windings are close by and you are using all of the toroid.

Hope you understand

Alan

Hi Dave,

I2C LCD displays on Arduino are easy once you get the correct library to match your I2C interface chip. A common chip is the PCF8574. You can get displays with this chip already installed from a number of retailers.

The link below is to the tutorial that I used to learn how to drive the PCF8574. There are PCF8574 libraries available on sources such as github as well as the source listed in the tutorial. However, the commands used in one library do not necessarily match the commands in another library and so the sketch code must match the library.

The biggest "gotcha!" is the I2C address of the PCF8574. You must have the correct address of the chip. If you do not know the address of the chip, there are sketches that will scan the I2C bus and display the results to the serial monitor. There is a link to an I2C scanner sketch in the tutorial.

http://tronixstuff.com/2014/09/24/tutorial-serial-pcf8574-backpacks-hd44780-compatible-lcd-modules-arduino/

<http://tronixstuff.com/2014/09/24/tutorial-serial-pcf8574-backpacks-hd44780-compatible-lcd-modules-arduino/>

<http://tronixstuff.com/2014/09/24/tutorial-serial-pcf8574-backpacks-hd44780-compatible-lcd-modules-arduino/>

Beware! Arduinos are addictive!

11710. Addwards A38-LMS Active Loop Antenna diagram added to Files

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-23 20:31:03 UTC
From: Steve Ratzlaff
Topic: 11710 Message: 11710

I have added my traced-out diagram of the Addwards A38-LMS Active Loop Antenna to the Files. Someone mentioned this antenna recently; I ordered one, tried it out then opened it up to try to trace the circuitry. It's apparently a variation of the Kaito D31 Active Loop Antenna, adding LW and MW.

I was primarily interested in its LW performance (stated as 120-400 kHz). The single-turn loop is 21.6 inches diameter--not a very large loop for LW usage. Using a stock Tecsun PL-380 pocket radio with the Addwards loop on LW I was only able to receive my very strongest local NDB (338 RYN, listed as 400 watts) about 12 miles away. And even the deaf PL-380 can receive RYN by itself, though the signal was boosted quite a bit by the Active Loop. Another 25 watt NDB about 15 miles away wasn't received. The Active Loop did peak the noise over the full tuning range of the loop, indicating it was working. A brief MW check indicated it wasn't very sensitive on MW either though better than on LW. I didn't try it on SW.

I did have fun tracing out the circuit though. :) It uses a two-transistor DC-DC converter operating at 2.4 MHz to step up the 3 volts battery voltage to 11.5 volts DC for the varactor tuning voltage. Note it appears to be more or less identical to the same circuit used in the Kaito D31 active loop, based on the traced-out circuit a German fellow did of the D31. (The SW specs of the A38 loop are given as 3.5-20 MHz so apparently the DC-DC converter isn't heard on any harmonics in the SW range though I didn't check.)

I don't have a Kaito D31 Active Loop to try, but it appears to tune only SW, so I have little interest in that. But based on my experience with the Addwards loop, unless you just want SW performance don't bother buying one.

73,

Steve AA7U

Hi Steve,

I was able to receive SB 396 15mi away, FCH 344 220mi, RYN 338, 398mi and a DGPS ~290 kHz after it got dark. Used my Sony 2010 rx with the included ferrite inductor and also plugged the loop into the AM antenna jack with the loop mounted outside in the clear. Nothing below 290 kHz. The LW switch position did not seem to do anything worthwhile (inop?). The MW switch position was much better for the NDB's. MW stations were OK. Did not check SW.

I guess it would be a cheap temporary/travel alternative as an outside MW antenna if you have nothing else and poor MW reception. The ~5m cable from the antenna to the amp was a plus. Received mine in about 6 days. I broke the little "L" on the loops spring clip straight away as it was too small for the loop antenna wire/coax (I forget if it is a wire or coax). So I just put the loop wire/coax in the jaws of the tiny plastic clip before hanging the loop. A wooden clothes pin with a spring would work just as well.

Even the cheap knock off mini-whip active antennas on the 'bay work way better with no switching or tuning. Interesting to play with for only US$20 but not a really serious antenna for Dxing.....

Many years ago I had a Russian radio (Vega Meridian), which used ferrite rods for all bands including SW. Although there was a telescopic whip as well, for strong stations the rod was perfectly good; I used it frequently at work for 31 and 49m.

IMHO, it's more challenging to write assembly level code as opposed to using these canned 'sketches'.

Hi Dave,
I2C LCD displays on Arduino are easy once you get the correct library to match your I2C interface chip. A common chip is the PCF8574. You can get displays with this chip already installed from a number of retailers.

The link below is to the tutorial that I used to learn how to drive the PCF8574. There are PCF8574 libraries available on sources such as github as well as the source listed in the tutorial. However, the commands used in one library do not necessarily match the commands in another library and so the sketch code must match the library.
The biggest "gotcha!" is the I2C address of the PCF8574. You must have the correct address of the chip. If you do not know the address of the chip, there are sketches that will scan the I2C bus and display the results to the serial monitor. There is a link to an I2C scanner sketch in the tutorial.

Hi
Thanks for the Response.
These are to Loop Stick Antennas that I bought on Ebay.
I found out later that they are from the Russian Meridian.
I plan to use the HF/SWL Stick as an experimental retrofit of a C. Crane AM
Twin Loop Antenna.
Later on my plan(s) are to augment or retrofit some vintage radios.

11718. Re: [loopantennas] loop antenna control

Yahoo group: loopantennas (2013 — 2017)
Date: 2016-12-25 23:06:45 UTC
From: Phillips
Topic: 11708 Message: 11718

Hi Dave,

I am approaching 70 myself. Even with an IT/programming background, I found the microcontroller world to be like operating in the fifth dimension. With time and experience, things came clearer. Still lotsa fog but clearer.

I found getting the LCD I2C working difficult because of the variability of libraries and their conflict with the standard Arduino compilers' libraries. That is why I offered to add the LCD code to your existing program.

The first thing to get clear is the type of the I2C interface chip. Once that is established things will go smoothly.

Then you need to put the correct library in wherever your store your arduino libraries. You may find that you already have a liquid crystal I2C library in your library folder. If you do, it would be best to move that whole library into an archive folder separate from the arduino software. This is because the compilers have a very good search process and will find all versions of a declared library whether you want them to or not and they are very pig-headed as to what library they choose to use.

Restart your arduino programming software so that it recognises the new library.

Within the code:

1.. At the top of the sketch is a place where libraries are declared. Add your I2C library here (#include <.....h>) You also may need to add #include <LCD.h> Here's a gotcha! Names in Arduino are case sensitive, you must follow capitalisation perfectly.

2.. Then you need to put in a backpack declaration. This varies from library to library eg

LiquidCrystal_I2C lcd(0x27,2,1,0,4,5,6,7); // 0x27 is the I2C bus address for an unmodified backpack

or

LiquidCrystal_I2C lcd(32,16,2); // set the LCD address to 0x20 for a 16 chars and 2 line display

or

others depending on how the libraries are written.

3.. In the " setup " section code put in your LCD initialisation code. Most libraries come with with an "examples" folder. You can copy the setup code from any of the examples that initialise the LCD.

4.. In the " loop " section you put your action code. When you want to write to the LCD, just specify the LCD location, clear what's there and write your new characters.

Please let me know if your LCD is using a PCF8574. If it is, I can put together a package of library and example code for you.

or

If you follow the tutorial link I sent, there are links to a library and sample code in there - should give you what you are looking for.

All the best,

Ray

No worries Dave. I can learn something myself. I've never used a rotary encoder and your code will give me an insight.

I won't alter any of your existing code - just add the counter and LCD display.

Your code is for an "EasyDriver" stepper interface module. I don't have one of these modules and so won't be able to test final code with the hardware. This should not be too much of a coding problem because the LCD code is passive and does not communicate back to the control code.

Her indoors has organised me for a number of inter-year activities but I will get to your code in the mornings before she wakes up. I have a spare Arduino and LCD already to go on the breadboard.

Don't worry too much about inexperience with Arduino code - it is a pain. The Arduinos are nice but the designers chose to use C++ as the coding language. C++ is a powerful language but has a whole lot of eccentricities that makes it sometimes confusing, but always pedantic and inflexible. To that add thousands of young men and women who were born with a C++ manual in one hand and a soldering iron in the other all contributing to the open source environment and we get a web of differing techniques and standards that can sometimes make the simplest Arduino operation difficult. Once you work out what works and what doesn't, Arduino becomes a lot easier.

What coding environment are you using? Is your PC running Windows? What version? Most people use the Arduino IDE. I found setting it up for the first time to be confusing but it works sweetly once it is running.

What Arduino are you using?

All the best,

Ray

Good evening Dave,

I too have pondered the same issue. The one that is the most important is to really know whether your capacitor is resonant above your receive frequency or below your receive frequency, so that you know which way to move the capacitor. The reason that I am pondering this is that I too have built an Octoloop (24 inches/side) for the LF - VLF range and it is to go on a pole out in the back yard which makes tuning the antenna much more difficult than if it were within arms reach. If the display could show even just an approx frequency of where the resonant freq is/was that would be better than not knowing where it was at all.

I like the Arduino approach. Can you keep me in touch with your progress?
Thanks and Happy New Year.

Fred - N4CLA

Fred,
One way to peel this onion (without crying) is to program the m/p to compute the frequency where the loop was last successfully tuned to resonance. Then, when it comes to re-tuning after a QSY, all the m/p has to do is to determine if the frequency is higher or lower and then move the capacitor in the proper direction. Trying to move the motor in the direction of decreasing SWR is a fools errand in that this approach will work only of the SWR is less that 8:1 (that was my experience).

Another way would be to 'sniff' the radio's frequency from the CI-V port, etc, etc. I did something like this with a Freescale chip a couple of years ago to automatically control an MFJ-1788 loop, but I stopped working on it because I couldn't get it to work properly over just the coax (had to provide a separate pair of wires for the motor).

I might go back to resurrect the first approach using a stepper motor, and re-code it for a PIC16f648A for which I have written a frequency counting routine that will work up to 40 Mhz.

There is a straightforward solution to this problem that was
first published at least 60 years ago: insert a phase discriminator
in series with the feedline close to the antenna. The phase
discriminator will generate a DC voltage having a polarity
indicating whether the loop is tuned above or below resonance.
You can use this to automatically tune the capacitor, or just
use the DC voltage as an indicator of which way to manually
move the capacitor. For further reading see, for example,:

Hey there - I tried this, and it didn't work with a mag loop when the loop is significantly out of resonance (when the coupling between the feed loop and the mag loop itself breaks down). Perhaps someone else can get it to work :-)

Yes, I can see where that might not work when you don't have a direct connection to the loop. Might be a reason to change to a direct connection type of matching network.

Hi Fred, the idea behind the nema stepper motor is that I set it up to micro step so that when I step it using a rotary encoder and the arduino I get 6400 steps per revolution (stepper has 0.9 degree steps)
using an lcd screen saves using the arduino ide to monitor the steps taken.
all you need to do then is go through the bands you want to use and note the steps needed for resonance .
if you first set up a start point at 0 steps all you need to do when wanting to start using the loop is return to the zero step point by pressing the encoder button function then increase the steps to the number needed then as you change band/frequency either increase or decrease the steps to the required number.
send me your direct e-mail and I'll keep you posted
regards
dave

Morning Joe,

I want to reiterate that this is NOT a Mag loop for T/R it is just a Rx loop, called an Octoloop for receiving the LF/VLF region. Having an extra set of wiring to the antenna is not a problem. I am currently using a FLEX 1500, and recently won an IC-7300 in a raffle that I have not tried in that part of the spectrum. Currently I have an analog stepper motor control for my capacitor using a belt and pulley, but would like to change it to a digital control direct drive where I can count the steps. I think that if I knew the step count and could correlate it to frequency, I would then know, looking at a chart, whether I was above or below the desired frequency, thus now moving the cap in the correct direction. Since this would be computed by some form of micro p, a display could possibly be added as well.

Just some thought provoking ideas.

Hi,
I just finished up a version of Graham Maynards active loop antenna and would like to feed the 12 volts to the circuit via the Coax line. I'm using the same voltage feed that I use for my mini-whip antenna to put the 12 volts on the coax. On Graham Maynards loop the first thing the voltage sees is the primary of the transformer i.e. dead short. Should I place a capacitor in series with the winding and center conductor of the coax to block the DC?? what value would be best if that's the case. I have a blocking inductor between the coax center conductor and the 12V rail of the circuit to block any signals coming back through the transformer. Thanks and happy new year to all!!

Hello Dave,

It may be that someone else has already done most of what you want. I was wondering if you are aware of this Yahoo group: https://groups.yahoo.com/neo/groups/loopController/info https://groups.yahoo.com/neo/groups/loopController/info

(Magnetic Loop Controller group or loopController group)

They have an arduino board set up for stepper motor control to tune a magnetic loop. It uses SWR sensing and frequency feedback from the radio. The group has been around for quite some time, and the operation of the hardware and software has been thoroughly tested. You may find the code/sketch you need in the files for that group. Or you might opt to buy the circuit board from Loftur (who manages the group), populate it, and then dump the code from that group into that hardware and go from there.

Regards ... Mark. N5KNG

Hello Rick

Thanks for the interesting link, and its useful references.

Pat Hawker, G3VA mentioned this issue in his Technical Topics column in the RSGB's Radcom, August 1989 Dick Kelsall, G4FM, had written to Pat discussing how he tuned his I1ARZ typ magnetic loop. Dick used his loop on three bands, and had coarse indication of the position of the tuning capacitor from a potentiometer which was mounted on it. However to get an indication of which way to tune within the bands he "introduced a phase detector into the coax feed..." It was made from an old SWR meter.

He did not say where he located the phase detector. I have always assumed that it was in the shack. Wouldn't one see a rapid change in the phase angle as you passed through the resonance point, regardless of the length of the transmission line? I need to think about this.

The general answer is that you would need to located the phase detector adjacent to the antenna. However, if the transmission line is less than 1/8 wavelength at the highest frequency of interest, you might still get a useful results if you locate it at the shack end.

If you use a longer line, you will see resonances that are a combination of the the line and the load. It may be that the rate of change of phase (AKA as group delay) peaks at the resonant frequency of the loop. However, that is no help if you are way off resonance and don't know which way to tune. The noise will always peak at loop resonance anyway, so you don't need the phase detector when close to resonance.

A simple way to match a loop is to connect the loop in series with the variable tuning capacitor, and connect this series combination to the output of the phase detector. The feedline goes to the input of the phase detector. There is also a fixed capacitor in shunt with the input of the phase detector.

For example, if the loop drive resistance is 1 ohm, the reactance of the shunt capacitor should be -j7 ohms, to match to 50 ohms.

In this case, the phase detector will tell you which way to tune when way off frequency, but would not indicate zero phase at resonance. You would need a second phase detector ahead of the shunt capacitor to do that.

In retrospect, the digital turns counter seems like the way to go. Several vendors already make these things for screwdriver antennas.

John,
The secondary winding is the one connected to the coax inner. Disconnect the grounded end of this winding and take it to the amplifier +ve. Connect the coax screen to the negative line on the amplifier.

Power going down the coax then passes to the amplifier through the transformer output winding. The amplifier negative connection then returns via the screen of the coax.

Terk AM loop at Amazon.com
Here is a place you can buy yourself a TERK AM loop antenna, even some other stuff that is kind of off topic to talk about. 73
http://www.amazon.com/exec/obidos/ASIN/B000069EUW/qid=1075080062/sr=2-1/ref=sr_2_1/102-8712984-4397719

WL1030 by the late Maartenhagg. Plans placed on this website by his friends in his honor.
http://wl1030.com/content/

C Crane Company
They sell the Justice AM Loop Antenna, Select A Tenna, Terk AM 1000
http://www.ccrane.com

Kiwa Electronics
Kwia makes the best products for you and your radio equipment, and also improves things that needed improvement a long time ago.
http://www.kiwa.com

Stormwise Ferrite Rods
Get some huge ferrite rods and a converter to go along with its, heck it even comes with project book.
http://www.stormwise.com

Universal Radio Company
They sell all sorts of loops big and small for LW/MW/SW and VLF also 10 kHz to 15 MHz
http://www.rffun.com

ALA-1530
Find the best UK LF/MF antenna here.
http://www.wellbrook.uk.com/

AOR
This is the site that sells the AOR loop
http://www.aorja.com/ant-e.html

Kiwa Electronics
The maker of the air core loop antenna and other useful items that you may want on your wish list.
http://www.kiwa.com

LF Engineering Company
A group of engineers, who make products for VLF/LF listening even ELF loops!
http://www.lfengineering.com

Select A Tenna by Intensitronics Corp
The maker of the select A tenna, a great AM loop antenna that is a little bigger than the terk
discontinued

Terk Technolegies
The maker of the best sold AM and I use also called the AM-1000 AM loop antenna, there is also technical information on how it works.
http://www.terk.com

Torus Tuner Loop Company
A very specially made loop that is almost as big as a hula hoop
discontinued

GRAHN (Germany) Specialized Loop Antennas for MW and SW Reception Contributed by radiohighfreq
Grahn offers both Ferrite Rod Antennas and Shielded Loop Antennas. Translated from the Gremany Language Webpages here is the "Grahn Specialized Loop Antennas for MW and SW Reception" ULR Address: http://www.grahn-spezialantennen.de/
Use the Google Translate a web Page Tool http://www.google.com/language_tools to convert these webpages to English.

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11738. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-01-01 14:27:16 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11738

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

> I just finished up a version of Graham Maynards active loop antenna and would like to feed the 12 volts to the circuit via the Coax line. I'm using the same voltage feed that I use for my mini-whip antenna to put the 12 volts on the coax. On Graham Maynards loop the first thing the voltage sees is the primary of the transformer i.e. dead short. Should I place a capacitor in series with the winding and center conductor of the coax to block the DC?? what value would be best if that's the case. I have a blocking inductor between the coax center conductor and the 12V rail of the circuit to block any signals coming back through the transformer. Thanks and happy new year to all!!

From: Jordan Dobrikin
Topic: 11741 Message: 11741

Hi
For Sony's: Bedside Reading & }No Antennas!{
For ultralites: What Radio(s) for modern days espionage?
For Antennas: What Antenna(s) best for Stealth & or Improved Reception?
BTW Happy New Year
73 de Jordan VE7JJD

http://cryptomuseum.com/spy/icf2001d/index.htm

Homepage Crypto Spy radio Stay-Behind Receivers
[Follow cryptomuseum on Twitter] [Watch cryptomuseum on YouTube]
Sony ICF-2001D
Portable short-wave receiver
The ICF-2001D was a portable solid-state LW, MW, SW and FM receiver, also known as a world receiver, made by Sony in Japan around 1980. Although it was a commercially available civil-class receiver, used by many people world-wide, it played an important role in international espionage.
The ICF-2001D measures less than 29 x 16 x 5 cm and is powered by two AA-size cells and three D-size cells. It has a built-in telescopic antenna at the top and a digital readout at the front. The device is commonly operated on its back, tilted by a bracket at the rear. This gives the optimum viewing angle for the LCD display.
The ICF-2001 can be powered by an external 4.5V DC adapter, or by the internal batteries. Alternatively, a 12V adapter cable was available to allow the radio to be used in a car. It was available in 3 different basic versions (types) [1].
Sont ICF-2001D
Furthermore, there were at least five country-specific models, each with their own frequency ranges. The device fully covers the LW and MW broadcast bands in AM, plus the VHF FM broadcast band (87-108 MHz). But the actual purpose of this radio is the Short Wave band (SW) that is divided in 13 segments from 2250 kHz (120 m) to 26.100 MHz (11 m). Unlike modern general coverage receiver, the SW band is not contiguous. It has small gaps in between the band segments and covers neither the regular amateur radio bands nor the 27 MHz (11 m) CB band.
This problem was solved in the later ICF-7600D that was introduced in 1983 and the slightly improved ICF-7600DS (1986), both of which have a general coverage from 153 kHz to 30 MHz (except for the German version which stops at 26.1 MHz). They too were used in espionage.
Sony ICF-2001D Sont ICF-2001D Operating the large tuning dial Operating the tuning dial with the index finger Close-up of the displays Tilt bracket at the rear Left side view Right side view
World receiver
Radio's like the Sony ICF-2001D and the Grundig Satellit 2000 were very popular in the 1980s. During the summer holidays in a far away country, it

allowed people to listen to the international broadcasts of their home country. In those days, most countries operated such a service on the SW bands, for example the BBC World Service. From the early 2000s onwards, most countries have gradually phased out their SW broadcasts, although the BBC World Service has remained in operation on analogue and digital platforms, broadcasting 24 hours a day in 28 languages [5].

FUNF, DREI, SIEBEN, ACHT, VIER...

Radio amateurs and SW-listeners will probably remember the mysterious number stations on the SW bands. A female voice that was reading endless sequences of seemingly random numbers for 24 hours a day, often in German or Russian. During the Cold War, many such numbers stations were operated by the secret services of the former Eastern Block countries, such as Russia (USSR), East Germany (DDR), Hungary, Czechoslovakia and Romania. The numbers were actually coded messages for their secret agents and spies that operated undercover in the west. In many cases the agent used a commercial receiver like the ICF-2001D for the reception of such messages.

Controls

The ICF-2001D has a clear and well-organised control panel that is located at the front of the unit or actually at the top when it is placed horizontally on the table. The main power switch is at the left side, with an additional switch to the left of the display. It also allows timer operation. The display consists of three sections: the real-time clock (left), the frequency readout (centre) and a signal strength indicator (right). The frequency tuning dial is in the upper right corner. it can be operated from the top as well as from the right. A slider at the right edge controls the volume.

Controls and connections on the ICF-2001D

The largest part of the control panel is taken by the keypad which roughly consists of five sections. The 32 black keys at the centre serve two purposes. They may be used to directly select one of the memory presets (8 presets divided over 4 banks). In combination with the blue shift button at the bottom left, these keys are also use to select the desired frequency band.

Above the black preset buttons are the MODE selectors. They allow selection between the FM and AM bands. In AM mode, the remaining buttons are used to select the desired modulation type (wide, narrow, sync, USB, LSB and CW). The row of brown keys just below the display are used for timer operation. The three white buttons at the left are used to activate scanning. The 11 white keys at the right can be used to enter the desired frequency directly.

Frequency bands

The ICF-2001D covers most broadcast bands on Long Wave (LW), Medium Wave (MW), Short Wave (SW) and Ultra Short Wave (here called FM).1 On some models even the Air Band is available.

LW : 150 - 285 kHz, in 3 kHz steps

MW: 531 - 1620 kHz, in 9 kHz steps; 530 - 1620 kHz, in 10 kHz steps

SW: 120 m, 2250 - 2550 kHz; 90 m, 3150 - 3450 kHz; 75 m, 3850 - 4050 kHz; 60 m, 4700 - 5110 kHz; 49 m, 5900 - 6250 kHz; 41 m, 7000 - 7400 kHz; 31 m, 9400 kHz - 10 MHz; 25 m, 11.500 - 12.150 MHz; 21 m, 13.500 - 13.900

MHz;
19 m, 15 - 15.700 MHz; 16 m, 17.450 - 18 MHz; 13 m, 21.350 - 21.950 MHz;
11 m, 25.570 - 26.100 MHz
FM: 76 - 108 MHz in 50 kHz steps (type 1) 87.5 - 108 MHz in 50 kHz
(type 2)
AIR: 116-136 MHz (AM) in 25 kHz steps 2
The Ultra Short Wave band (76-108 MHz) is officially designated the
Very High Frequency band (VHF), but is better known as FM (Frequency
Modulation) after the wide-band modulation art that is commonly used in
this broadcast band.
The AIR band is just above the FM broadcast band and is only available on
certain models. AIR broadcasts are generally in AM (Amplitude Modulation).
The Red Colonel
The ECF-2001D as a spy tool
Due to its small size, its high sensitivity and the fact that it was
battery powered, the ICF-2001D was often the receiver of choice for
East-European spies operating in West-European countries during the Cold
War. In many cases, Eastern-Block espionage agencies, such as the KGB, the
GRU and the Stasi, gave their western spies money in order to buy such a
receiver in a local shop.
The receiver was used by the spy to listen to the East-European number
stations that operated on the Short-Wave band (SW). Hidden in the numbers
were secret messages and instructions for the spy, that were encrypted with
the unbreakable One-Time Pad. Once the spy had decoded his message, he
would destroy it and carry out his mission. Messages were sent back to the
spy control centre by means of a courier, dead letterboxes or a clandestine
spy radio transmitter.
An example of the use of this radio is the case of Guy Binet (1934-2000), a
colonel of the Belgian Army, who was recruted in 1986 by the Soviet
Military Intelligence Service, the GRU. On the first meeting in Vienna with
his handler, GRU General Glazkov, he is given a Minox EC spy camera.
He uses the camera to photograph secret NATO documents and delivers the
films to the Russians in Vienna in January 1987. That week he is also
trained in deciphering secret radio messages. He receives a One-Time Pad
cipher table {hidden in black Snowman marker) and a frequency table.
ICF-2001D, Minox EC and one-time pad [What is this?]
He is also given a large sum of money and is instructed to buy a Sony
ICF-2001D on his return to Belgium [3]. Every second and forth Tuesday of
each month, Binet listens to the coded messages that are transmitted by the
mysterious number stations on the short wave radio bands.
Sadly for Binet, the American Intelligence Agency CIA has photographed his
first meeting with Glaskov in Vienna [3] and tips-off their Belgian
colleagues of the SDRA III, after which Binet is arrested. By that time
however, Binet has been spying for the Soviets for more than two years. He
becomes known as The Red Colonel [4] and is eventually sentenced to 20
years of forced labour and military degradation. After five years in prison
he is released on parole and dies in July 2000.
➤ More about Binet's Minox EC camera
Attencion!

Spying for the Cubans

Another example of the use of the ICF-2001D in international espionage, is a series of cases against US citizens between 2001 and 2009. In each case, the subject(s) had been spying for Cuba, and the FBI found a Sony ICF-2010 (the US version of the ICF-2001D) in their homes.

The first case is that of Ana Belén Montes (28 February 1957) who worked for the US Defence Intelligence Agency (DIA) as its most senior Cuban analyst [6]. She had been spying for Cuba since 1985 until her arrest in 2001, during which time she had passed numerous documents and sensitive military information to the Cubans.

Prior to her arrest on 21 September 2001, the FBI had searched her appartment and found evidence of the use of One-Time Pade (OTP) messages on her laptop. Also present in the appartment was a functional Sony short-wave receiver that was used to receive OTP messages from the Cuban Numbers Station on 7887 kHz.

Evidence for this was found on her Toshiba laptop. Although she had clearly been instructed by the Cuban Intelligence Service, the CuIS, to run a special program to wipe the data from her laptop after use, she had failed to do so [7][8]. As a result, the FBI was able to retrieve a large OTP message, consisting of 150 5-digit groups.

Ana Belén Montes, FBI mugshot. 21 September 2001. [What is this?]

According to author Keith Melton, who is a well-informed US intelligence source, Montes used a Sony ICF-2010 [9], which is the US equivalent of the ICF-2001D featured here. In a detailed paper of 2010, researcher Dirk Rijmenants explains how the FBI managed to break the seemingly unbreakable OTP cipher due to flaws in the Cuban procedures [8]. After pleading guilty to spying, Montes was sentenced in October 2002 to 25 years in prison without the chance of parole [1].

Similar cases are those of Carlos and Elsa Alvarez (caught in 2006 after spying for 30 years), Marta Rita Velazquez, Gerardo Hernández (one of the Cuban Five) and Walter Kendall Myers and his wife Gwendolyn Steingraber Myers (arrested in 2009 after spying for nearly 30 years). In all cases, the ICF-2001D was used to receive the coded messages from Cuba's Attención Station. Interested in more stories? Check out the FBI 100 [10] or the website Cuba Confidential [11].

11742. initial obeservations and questions Re: Graham Maynard 6X6 loop.....

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-01-06 00:42:05 UTC
From: J Ferrow
Topic: 11742 Message: 11742

Not bad, but not great either. it's good on MW and 160khz all the way to 7 MHZ about where sensitivity starts to fall off, but it's a bit noisy from 150khz to the AM BCB where i am most interested in. It does receive the long wave broadcast stations well, but the backround buzzing noise does get annoying. I did not connect the center tap portion of the transformer to the mid way point on the loop, but instead just left it grounded. Would not connecting the center tap cause this antenna to be noisey?? Also too big a loop and it overloads hearing many BCB stations in the LW spectrum. I have a wellbrook ana-100LN on the way and am looking forward to comparing the two. Any suggestions for optimizing the Graham Maynard loop?? Do multiple turns on the loop make a difference in operation vs. just one turn?? I understand more antenna in the air, but does it matter much when the spacing of the multiple turns is so close?? Thanks for reading.
Happy 2017!!, John in FLA

That was the date of his address change.

His General license was renewed in 2015, and in 2005. Before 2005, I can't tell. I think it was not in the ULS before then.

Hi
I am looking for the Schematics of the Select A Tenna with Antenna Jack, as well as the Terk and Tecsun Loop Antennas.
I am trying to figure out how best to use them with multi Inductor Crystal Radio ensemble.
I am looking at Variometers, Variocouplers as well as a ferrite Loop to be driven by a C.Crane Twin coil mounted outside on an Antenna rotator.

Hi

Try the Yahoo Group ultralightdx. Home of of the Ferrite Sleeve Magnetic Loops.
There are several You Tube Videos on these loops.

You are starting out at a disadvantage indoors, hopefully a wood building as opposed to a Concrete/Steel building.

For air Loops, the larger size/AREA the better. The bigger the Loop the more signal collected.

Consider an OUTDOORS, Remote, Varactor Tuned, Wide Band Low Noise Preamplifier

Hi Rinus,

Homes on the grid are filled with RF noise sources- switching power supplies such as wall mount transformers, LCD displays, PC's and almost every domestic electrical appliance and the wiring. When you put any kind of antenna close to these devices you will hear them very well but not be able to hear weak external signals. A bit like trying to see the stars in the night sky from inside a brightly lit smoke filled room with dirty windows.

The complete answer is to move the antenna to an electrically quiet location i.e. outside a house. Noise fields drop off very rapidly with distance, moving 10 or 15 M/Yards away makes a vast difference. I would suggest that a portable radio tuned to the LF end of the MW makes a cheap survey tool, if you listen in possible antenna locations around noon you can soon find quieter locations. (mid-day listening = no distant signals so you can better hear the local noise!)

If you want to excel then you use the radio to locate and remove every noise source you can. You might find the odd laptop supply is very noisy or the odd aging low energy bulb. There are a range of noise reducing methods involving filtering which can be found in Ham radio publications if you want to push the limits.

Low noise antennas are a bit of a contradiction! you can have shielded loops that tend to reject electric fields and you can use directional antennas to avoid noise from some directions but there is not an antenna that is sensitive to weak distant signals yet will not hear strong local noise sources excepting in the world of advertising.

NDB's are a good test, with a loop OR an E-field active antenna 14M from my house I can always hear BIA or SA in Poland from near London UK . When conditions allow - 5/10W 160M transatlantic stations using WSPR. WSPR is a very interesting mode, it is a great test of receiving ability and you get real signal to noise numbers for your setup and those of everyone else via the database. That is very helpful as you can compare the results of changes in your set-up. WSPR does need a very stable (probably synthesised) receiver.

There is some very useful free software which is widely used for hunting very weak sub-audible signals, perhaps the easiest is Spectran. You send the received audio to a laptop or PC then you can see very low level signals on screen, read frequency and amplitude of the audio and see the nature of incoming signals, great for resolving slow Morse from NDB's or for learning about unknown signals.

Happy hunting.

Alan

Dear Jordan and Alan
Thanks a lot for the tips you gave me
i will try your suggestions
The last period i have read a lot about Loop antennas
Concerned the air loops i understand there are two kind of loops
the , for example, 4 foot box loop with spacings between the windings
and the other...
the spiral loop, the windings, also spaced, but are flat , as in a spiral
what will be the difference?
Regards
rinus

Hi
The spiral coplanar will give a lower over all Area. This will more significant with Long Wave which calls for a longer length of wire than Medium Wave.

The Solenoid, Box Loop, retains large Area. It increases the the distributed capacitance which decreases the the resonant frequency; not a problem as the required variable capacitor will be adding a lot more capacitance.

http://www.angelfire.com/mb/amandx/loop.html This one is interesting in that it rotates in two planes.
http://makearadio.com/loops/ Dave's Homemade Loop Antennas examples of spiral and box loops.

Frame construction skills and visual esthetics of others using the Living Room come into play.

Wire selection is a toss up Litz is used on ferrites and occasionally on Air Loops. Consider heavy gauge solid copper that holds it shape when bent, making easier on a simpler frame.

Consider getting a Large cardboard box from the the local supermarket use as a frame for a prototype antenna both Box and Spiral on the same box. Also consider a Larger box like a Moving Company Wardrobe Box.

Cover the box with a cloth slip cover that fits the decor of the Living Room. Or even an outdoor Stealth Antenna on patio porch balcony or what have you.

Hi again,
The Spiral winding is simpler to make but the electrical balance is not so good as the type with parallel winding. Turns can be bundled together however the Q is decreased and the additional capacitance caused by close turns restricts the HF tuning range. You can use multi conductor cables by connecting the wires into one continuous winding but the self capacitance is very high and the Q is often quite low.

There are more kinds than TWO !! A very good option is to use a metal shield to contain the winding with an insulated gap. This was very widely used in Direction Finding, the screen helps force the capacitance of each side of the loop to ground to be similar and to reduce stray pick up. That gives clean nulls 180 degrees apart.

A variation is to use a single turn loop and a tuned transformer coupling to the receiver. That can be every bit as good as a multi-turn tuned loop but is far more convenient, by switching turns and/or using added inductance a single loop can cover a very wide frequency range. This single turn loop can also be well balanced to ground by grounding a centre tap on the transformer primary. Most DF receivers tightly couple the loop to a tuned transformer which can be switched for different bands, Aircraft DF receivers cover around 190-1750 KHz in three bands for example.

Another form is the single turn or two turn active loop where the loop is connected to a very low input impedance amplifier to produce a very wideband loop that is untuned, slightly less sensitive than the tuned loop but in any loop application below a few MHz you might be limited by the natural noise background.

There are other kinds of loop but perhaps a bit specialised.

8' Loop Styrofoam Crystal Radio Part 3
josh8loop
Published on Aug 19, 2012
This is the makings of an 8' Styrofoam 660/46 Litz double tuned loop
crystal radio. It features a round 8' aperture for signal capture. The main
loop will be using a six turn primary 8' in a Contra-Wound configuration to
allow easy band spread with two distinct inductance values from the main
loop winding. The main loop will also use a 4-gang variable capacitor in a

wiperless configuration which if my prior loop experience pans out will
allow the loop to remain electrically "balanced". I have experienced this
wiperless-induced balance before in a previous variant of a large loop, and
it has exceptional Q enhancing abilities among other attributes. I fully
expect that this loop with the quality materials and construction methods
employed will resonate and re-radiate RF with a bandwidth of around 30-40
KHz which should drastically enhance inductively coupled secondary
selectivity. The secondary or "detector" portion will use a ferrite
assisted air coil and a high quality silver/ceramic single gang variable
capacitor and an Advanced Linear Devices Zero Bias FET and a separate tank
source winding to demodulate the audio from the RF. The styrofoam used to
make the ring was purchased from an architectural styrofoam manufacturing
company that uses a "Hot Wire" type CNC machine to create various styrofoam
profiles. Future videos will show additional construction techniques and
details of the "detector" portion among other aspects.

Terk Advantage loop antenna is 8 turns of wire on a 12-inch diameter form. The usual AM tuning capacitor is soldered in parallel with this coil. The 1/8"/3.5mm jack is connected to a single turn loop in parallel with the 8-turn loop. The single turn loop can be connected to an antenna and ground connection or use to inductively couple the loop to the BCB receiver. When used with a multi-inductor xtal radio, the Terk can also be used as trap filter for undesired/nearby transmitters with one connection from the 1/8" plug towards the antenna and the other to the antenna input of the xtal radio.

Hi Rinus,
Tuned circuit Q is sometimes called the "Quality Factor", it's how sharply the circuit resonates. So if you had a loop resonant at 1MHz (1000KHz) and a Q of 50 it will have a "bandwidth" of f/Q = 1000/50=20 KHz between the tuning points where the output is at half the peak power (-3dB).

Q has a multiplying effect on received signals, a loop with a working Q of 200 will deliver four times (+12dB) more signal than a working Q of 50. This gain is noiseless unlike an active amplifier. A Q of 100-200 is not difficult to attain in a home made loop. If you had a 1m square loop of around 7 turns with a 500pF air spaced tuning capacitor with a 1 turn coupling loop to the receiver you should tune MW OK. More turns for LW, if the turns are around 5mm or 1/4" apart then the Q will be good, bundling the turns will greatly increase their capacitance and reduce the HF end of the tuning range as well as reducing the sensitivity.

There are Q meters available but they are a bit rare these days. A SDR receiver and a signal generator can be used, you find the two frequencies where the loop output is 3dB down, subtract to get the bandwidth then divide the mid frequency by the bandwidth to reveal the Q number. A very rough test is how sharp the tuning is- if you wished the tuning knob was a lot bigger or you had a reduction gear because the tuning is sharp then you have a highish Q!!

I would seriously suggest that you make your gear portable so you can experience the vast difference getting away from household wiring and appliances makes, there is a day and night difference!

As said a little transistor MW radio is a useful tool for detecting noise from wiring , bulbs, wall warts and many other appliances, you can quickly find the main noise generators. If you have battery powered gear then it might be worth just switching off all of the power for a few moments to kill all of your own local noise and hear what happens.

Good DX,

Alan

HI
Good explanation and advice.

Most all radios will benefit with a good RF Ground Spike in the earth best, Clamp to metal Cold Water plumbing, or connection to House wiring Neutral/Ground.

Battery operation avoids noise coming through the AC wiring, noisy Wall Warts. You want Low Self Discharge batteries Rechargeable Alkaline or NIMH ENELOOP

Some noise reducing Ferrites on noisy appliances won't hurt. TV power cord, Computer & and Monitor cords, etc..

Dear Rinus,
Domestic noise is increasing indoors these days and if you want receiving indoors it will pick up the electric and magnetic noise component from switch regulator and alike.
If you want to suppress the domestic noise the best way is probably installing the ferrite loop above the roof noise level away from the source.
For indoor installing a ferrite loop antenne you can screen the loop for the electric field with a thin static wire screen not making short-circuit the RX field and so reduce the parasitic capacity and maintain the Q factor of the loop windings.
The noise from the electric field is reduced that way. Bud there is also noise in the magnetic component that may be reduced by turning the loop to de magnetic NUL from the source.

For an large air loop the windings should be screened also and that can be done with a RG214 coax loop and use the outer screen. On top it has a small open cap and not shorted the fields. The inner will be the loop itself and taken out from a small center gap below in the screen. The screen should below connect to ground.
A good description how to screen a ferrite loop can be found on this site from PA2OHH http://www.qsl.net/pa2ohh/07fer.htm http://www.qsl.net/pa2ohh/07fer.htm handling this problem.
I have a professional Bendix ferrite loop antenne from an air craft automatic LW beacon direction finder with use also PA2OHH his thin wire screening technique.

Hi, Not a specific loop antenna question, but I have this pulsating "snaking" noise on my perseus spectrum from about 10 khz to approx.190 khz. It's worse in some areas such as its really bad around 180 to 190 khz, the area of the ham experimental beacon bands. I used a battery to power my loop and whip amplifier thinking it was maybe coming from the amplifiers wal-wart, but its still there. I isolated my perseus 5 volt wal wart with an isolation transformer, but that doesn't help. i'm running my computer off it's battery and even moved my whip antenna on to the fairway of the golf couse i live on, pretty far away from any possible emi and its still there. Is this just naturally occuring noise? is there any way to smooth or filter it out as I would like to listen for beacons on the experimental band. thanks
John in FLA

Greetings Rinus. To search out noise sources use a small transistor radio as a "sniffer". Take the receiver, extend the telescopic antenna about 200mm, tune off a station so that you receive noise. Use the setup as a "wand", like Harry Potter, moving it around electrical items. You do not need to turn things off. you will soon sniff out noise sources. Regards Max vk2tti.

Hi Alan
Thanks a lot again , that you take the effort to make things clear for me
I really appreciate it.
And i understand it, what you write.
But it brings up new questions...
Has the used wire also influence on the Q?

and is there a relationship or ratio between the size of the loop, how much windings, spacing, wire's used, capacitance
and the frequency area where the loop is designed for?
is there somewhere a diagram , where one can read :< for example>...
i want to make a loop for VLF
which size do i need, how many turns, which wire , how much capacitance?
is there a ratio?< is that the right word?>
Regards
rinus
and i will provoke complete power shutdown,,,locally....and see what happens to the signals..

Hi Rinus,
Tuned circuit Q is sometimes called the "Quality Factor", it's how sharply the circuit resonates. So if you had a loop resonant at 1MHz (1000KHz) and a Q of 50 it will have a ";bandwidth" of? f/Q = 1000/50=20 KHz?between the tuning points where the output is at half the peak power (-3dB).

Q has a multiplying effect on received signals, a loop with a? working Q of 200 will deliver four times (+12dB) more signal than a working Q of 50. This gain is noiseless unlike an active amplifier. A Q of 100-200 is not difficult to attain in a home made loop. If you had a 1m square loop of around 7 turns with a 500pF air spaced tuning capacitor with a 1 turn coupling loop to the receiver you should tune MW OK. More turns for LW, if the turns are around 5mm or 1/4" apart then the Q will be good, bundling the turns will greatly increase their capacitance and reduce the HF end of the tuning range as well as reducing the sensitivity.

There are Q meters available but they are a bit rare these days. A SDR receiver and a signal generator can be used, you find the two frequencies where the loop output is 3dB down, subtract to get the bandwidth then divide the mid frequency by the bandwidth?to reveal the Q?number. A very rough test is how sharp the tuning is- if you wished the tuning knob was a lot bigger or you had a reduction gear because the tuning is sharp then you have a highish Q!!??

I would seriously suggest that you make your?gear portable so you can?experience the vast difference getting away from household wiring and appliances makes, there is a day and

night difference!

As said a little transistor MW radio is a useful tool for detecting noise from wiring , bulbs, wall warts and many other appliances, you can quickly find the main noise generators. If you have battery powered gear then it might be worth just switching off all of the power for a few moments?to kill all of your own local noise and hear what happens.

Good DX,

Alan

I have been using a 3-ft square tuned loop for 150 to 440 kHz with great success for many years. This is a "pancake" loop, wound in a single plane. The coil consists of 80 turns of 22 AWG stranded wire. It is woven tennis-racket style on a wooden cross with holes drilled every 1/4 inch. The coil and tuning capacitor rotate 360 degrees laterally and 90 degrees vertically in order to produce excellent nulls in any direction.

There are a few basic points you need to consider. The signal is picked up by the coil. The capacitor is just there to provide resonance to the circuit. The values of inductance and capacitance at a given frequency are inversely proportional. Therefore, the tuned circuit should have the highest L/C ratio possible in order to optimize pickup.

In order to minimize capacitance, some effort should be made to lower the distributed capacitance of the coil. The distributed capacitance is partially a function of the shape of the coil. Given the same inductance, a pancake coil (vs. a solenoid shape) will have the least distributed capacitance.

You can feed the coil/capacitor with a characteristic low impedance in series with the transmission line. This however will place the transmission line and receiver in series with the tuned circuit at resonance and effectively lower the Q. My loop is fed from a pickup coil (3 turns, 8-inch diameter) mounted in the center of the primary coil. The primary coil and pickup coil thus form a transformer. This allows the main coil and capacitor forming the tuned circuit to "freewheel" in space under minimal load, and preserves the high Q. In fact, Q is high enough that the circuit must be repeaked every kHz.

Hi Rinus,

I thought that I might add my two cents' worth.

I have experimented with air loops of varying size and configuration both inside and outside as well as ferrite rod antennas of varying configurations such as 580mM single rod, 200mM single rod and 3.5" FSL's.

For a first-time DX'er I would recommend a 200mM ferrite rod antenna using cheap Litz wire. I say this because it is relatively easy and cheap to build, convenient to use and provides good performance for its size. You can add shielding, rearrange the windings or use higher performance litz, easily at a later time. As your experience and expertise blossom, you may consider making additional antennas but the 200 ferrite will provide a good start.

There is a wealth of information on ferrite rod antennas on the 'net - search "ferrite rod antenna construction". Unless you can use identical parts in constructing an existing loop, there are so many variables that some experimentation is inevitable. If you begin with the mindset that "I am going to have to do some experimentation", you will be better equipped to get the best out of your components. One trick that I use is to wind more turns than I think I will need and then take turns off until it tunes as I want (removing turns is a lot easier than trying to add them).

As for power outages - they are a blessing. In my part of suburbia, the man made noise is horrific. When the power goes out (not often enough - curse the efficient distribution company) a whole new world of RX opens up. But then getting away from the noise is a good excuse for trips to the wilderness. Another reason for a 200mM antenna - it is highly portable - even taking it to the park can sometimes get rid of a lot of man made noise. Carrying a 4 foot square air loop to the park is great for aerobic fitness but not for convenience.

Looks like my two cents turned into two dollars. No matter, whatever path you finish up taking, I hope you get a lot of pleasure and satisfaction,

Ray

Hi John,

Why not DF the noise? Turn the loop until the noise is minimal then check that the other null is exactly half a turn around. The signal is then exactly broadside (90 degrees) to the turns. If you can't find a null it's the gear! Several bearings from different locations should reveal the source but best done during the day when no skywaves around..

Not sure what the noise sounds like, if it is a click the could be an electric fence, buzz could be a power line fault - often weather dependant.

Hi Rinus

Litz wire provides higher Q over a limited frequency range around MW frequencies - at LF and HF the improvement is often not worth the much higher cost for a hobby user. You also have to be sure that you connect to every strand of the enameled litz strands at both ends otherwise the enhancement in Q can be lost. Regular 16/0.2 PVC insulated " hook up" wire works well for nearly all air cored loop use certainly it is good enough to use to get you going and is much easier to obtain and use.

I outlined a MW 7 turn loop in the last post. Putting on twice the number of turns will increase the inductance four times (L proportional to turns squared) so that if a 7 turn loop tunes down to 500KHz then a 14 turn loop will tune down to 250KHz approximately with the same tuning capacitor. Large loops need wire! A 7 turn 1m sided loop needs 1m x 4 sides x 7 turns = 28m of wire. Air spaced tuning capacitors from an old AM MW radio have advantages- higher Q and you can see from the meshing of the vanes how much C you have.

However people worry about loop size- it is not as important as WHERE you put it, what you hear is limited to the amount of noise against the signals you want to hear. Beyond a set size you don't improve the signal to noise- only make both bigger. Giant loops only make sense in very quiet country locations with NO overhead lines for miles. Even there you get to the point where atmospheric noise becomes the limit. A 1m /1 yard sided loop of modest Q should reach the noise floor in many locations from 100KHz to 1600 KHz.

Throw something together this weekend from whatever you have around and get listening!!! It does not have to be perfect immediately. You have not said what kind of receiver you have. These days I would strongly suggest a SDR & laptop combo, you get so much more information from the screen and can see signals you can't hear. They are very good for NDB's at extreme range. But any radio with an audio out can be used with Spectran on a laptop to give exceptional sensitivity and a waterfall display ideal for weak signal work.

Get building & listening!! you can make a simple loop with a wooden cross then use cable ties or string to hold the windings to the wood in a spiral fashion- quick and effective. Then you could use cross arms to allow the turns to be parallel as a follow up. (If you can- best to do both and compare how they work by swapping one to the other much more meaningful than trying to remember how it worked- always misleading).

Alan

Hi Alan, Thanks for the suggestion. I have noticed that getting the loop up in the air eliminates some of the noise. I'll try and rotate it tomorrow and get it up in the air higher and see where the noise source is coming from and if the extra height helps more also. For this particular loop I'm using the wellbrook ala-100 LN amplifier. Currently I have about a 20 meter circumference loop on a PVC "cross". The plan is to make two loop "crosses" at right angles and use a relay to switch between the two to make it more directional. i would like to make the circumference bigger, but unfortunately i have neighbors on either side of me so if i make it too big i'll pick up more and more noise. perhaps if I make the cross out of large wood dowels people use to hang curtains and such i can get some more circumference due to the better rigidity of the wood . I know some dx'ers are using 100 ft + circumferences and more. for me smaller is manageable and will allow me to move the loop and get it up higher as to null the noise as you suggested. Thank-you again.
john

Hi
The "wire" is Key in all small magnetic loops.

The name of the game is maximum surface area AC/RF travels on the outer portions/surface of a conductor, even at 60 cycles where high voltage transmission lines are a hollow core.

That is why you see Copper Pipe and other metallic strips, bar stock and ribbon on transmitter loops as well as commercial receive loops like Wellbrook & others. These loops depend on low noisw differential amplifiers to give their wide frequency range

Litz wire the ultimate multi strand maximum surface area is good up to the top end of the MW Band. However its a bit pricey especially in VLF, & LF where you need a lot of wire length. It's a bit flimsy for larger open air loops and obviously limited to indoor use. Litz comes in several grades with the lowest cheapest grade most likely better than stranded wire

Stranded wire is better than solid wire.

You really don't need a formula as the frame will determine how much wire you can use, IMHO.

For VLF/LF a spiral loop is mechanically impractical, again IMHO.

For a solenoid loop you probably will not be able to wind a single layer so wire spacing becomes moot, again IMHO.

Hi John, any chance it could be solar panels with a nasty cheaply built inverter, have seen this a few times lately and a rotated loop found the inverter placement.

Dear Alan
Again thanks and again, you, and other on this list ,?make things very clear for me
I have the following equipment:
several portables as sony 7600 GR and Sangean and Degen 1103
but also Icom 8600 and also ELAD FDM -S2 SDR
i think you will be satisfied ...hihi, also i have60; a FT-817 yeasu

About building soon...i have the following wires in my junkbox...
PVC 24/0.2 mm wire,,,approx 80 meters

660/# 46 m?? 0.04 mm litz wire?60;? approx.60 feet
and
stranded? speaker wire 0.75 mm2? with transparent/clear insulation? approx 100 meters

also several , up 700 pF, capacitors from old radios

also i have a ala 1530 loop but not useable indoors...

this week i will start with checking the noise sources
Regards
rinus

Hi Rinus

Litz wire provides higher Q over? a limited frequency range? around MW frequencies - at LF and HF the improvement is often?not worth the much higher cost for a hobby user. You also have to be sure that you connect to every strand of the enameled litz strands? at both ends otherwise the enhancement in Q can be lost. Regular 16/0.2 PVC insulated " hook up" wire works well for nearly all? air cored loop use certainly it is good enough to use to get you going and is much easier to obtain and use.

I outlined a MW 7 turn loop in the last post. Putting on twice the number of turns will increase the inductance four times (L proportional to turns squared) so that? if a 7 turn loop tunes down to 500KHz then a 14 turn loop will tune down to 250KHz approximately with the same tuning capacitor. Large loops need wire! A 7 turn 1m sided loop needs 1m x 4 sides x 7 turns = 28m of wire. Air spaced tuning capacitors from an old AM?; MW radio have advantages- higher Q and you can see from the meshing of the vanes how much C you have.

However people worry about loop size- it is not as important as WHERE you put it, what you hear is limited to the amount of noise?against ?the signals you want to hear. Beyond a set size you don't improve the signal to noise- only make both bigger. Giant loops only make sense in very quiet country locations with NO overhead lines for miles. Even there you get to the point where atmospheric noise? becomes the limit. A 1m /1 yard sided loop?0;of

modest Q should?reach the noise floor in many locations from 100KHz to? 1600 KHz.

Throw something together this weekend from whatever you have around and get listening!!! It does not have to be perfect immediately. You have not said what kind of receiver you have. These days I would strongly?suggest ?a SDR & laptop combo, you get so much more information from the screen and can see signals you can't hear. They are very good for NDB's at extreme range.? But any radio with an audio out can be used with Spectran on a laptop to give exceptional sensitivity and a waterfall display ideal for weak signal work.

Get building & listening!! you can make a simple loop with a wooden cross then use cable ties or string?to hold the windings to the wood in a spiral fashion- quick and effective.? Then you could use cross arms? to allow the turns to be parallel as a follow up. (If you can- best to do both and compare how they work by swapping one to the other much more meaningful than trying to remember how it worked- always misleading).

Dear Ray
i am very happy with your answer , Much more worth, than money, for me !
If you write: a 200 mM single rod, i think you mean a rod of 20 cm...?
and is your suggestion for MW, or LW or both?
do i also need a capacitor of 700 pF with it?
and do i need also a amplifier with it\
how many turns of wire do i need approx

i am certainly willing to make it and experiment with it , but the same as with loop antenna's...
the problem i encounter is the very large amount of information
i am flooded through it..
that's the reason i started asking you on this list,all this questions

Again thanks
Regards
rinus

Hi Rinus,

I thought that I might add my two cents' worth.

I have experimented with air loops of varying size and configuration both inside and outside as well as ferrite rod antennas of varying configurations such as 580mM single rod, 200mM single rod and 3.5" FSL's.

For a first-time DX'er I would recommend a 200mM ferrite rod antenna using cheap Litz wire.? I say this because it is relatively easy and cheap to build, convenient to use and provides good performance for its size.? You can add shielding, rearrange the windings or use higher performance litz, easily at a later time.? As your experience and expertise blossom, you may consider making additional antennas but the 200 ferrite will provide a good start.

There is a wealth of information on ferrite rod antennas on the 'net - search "ferrite rod antenna construction".60; Unless you can use identical parts in constructing an existing loop, there are so many variables that some experimentation is inevitable.? If you begin with the mindset that "I am going to have to do some experimentation", you will be better equipped to get the best out of your components. ?One trick that I use is to wind more turns than I think I will need and then take turns off until it tunes as I want (removing turns is a lot easier than trying to add them).

As for power outages - they are a blessing.? In my part of suburbia, the man made noise is horrific.? When the power goes out (not often enough - curse the efficient distribution

company) a whole new world of RX opens up.? But then getting away from the noise is a good excuse for trips to the wilderness.? Another reason for a 200mM antenna - it is highly portable - even taking it to the park can sometimes get rid of a lot of man made noise.?; Carrying a 4 foot square air loop to the park is great for aerobic fitness but not for convenience.

Looks like my two cents turned into two dollars.? No matter, whatever path you finish up taking, I hope you get a lot of pleasure and satisfaction,

Ray

Hi Alan
Thanks a lot again , that you take the effort to make things clear for me
I really appreciate it.
And i understand it, what you write.
But it brings up new questions...
Has the used wire also influence on the Q?

and is there a relationship or ratio between the size of the loop, how much windings, spacing, wire's used, capacitance
and the frequency area where the loop is designed for?
is there somewhere a diagram , where one can read :< for example>...
i want to make a loop for VLF
which size do i need, how many turns, which wire , how much capacitance?
is there a ratio?< is that the right word?>
Regards
rinus
and i will provoke complete power shutdown,,,locally....and see what happens to the signals..

Hi Rinus,
Tuned circuit Q is sometimes called the "Quality Factor", it's how sharply the circuit resonates. So if you had a loop resonant at 1MHz (1000KHz) and a Q of 50 it will have a "bandwidth" of? f/Q = 1000/50=20 KHz?between the tuning points where the output is at half the peak power (-3dB).

Q has a multiplying effect on received signals, a loop with a? working Q of 200 will deliver four times (+12dB) more signal than a working Q of 50. This gain is noiseless unlike an active amplifier. A Q of 100-200 is not difficult to attain in a home made loop. If you had a 1m square loop of around 7 turns with a 500pF air spaced tuning capacitor with a 1 turn coupling loop to the receiver you should tune MW OK. More turns for LW, if the turns are around 5mm or 1/4" apart then the Q will be good, bundling the turns will greatly increase their capacitance and reduce the HF end of the tuning range as well as reducing the sensitivity.

There are Q meters available but they are a bit rare these days. A SDR receiver and a signal generator can be used, you find the two frequencies where the loop output is 3dB down, subtract to get the bandwidth then divide the mid frequency by the bandwidth?to reveal the Q?number.? A very rough test is how sharp the tuning is- if you wished the tuning knob was a lot bigger or you had a reduction gear because the tuning is sharp then you have a highish Q!!60;?

I would seriously suggest that you make your?gear portable so you can?experience the vast difference getting away from household wiring and appliances makes, there is a day and night difference!

As said a little transistor MW radio is a useful tool for detecting noise from wiring , bulbs, wall warts and many other appliances, you can quickly find the main noise generators. If you have battery powered gear then it might be worth just switching off all of the power for a few moments?to kill all of your own local noise and hear what happens.

Good DX,

Alan

Hi
You out gun me I use the Sony ICF 2010/2001D and the close 2nds Radio Shack DX 440 and Sangean ATS 803a.

Also refurbishing some antiques, Westinghouse RADA, Radiol IIIA, Steinite Crystal Radio and Sears Silvertone TRF Neutrodyne 8 tubes 4 RF Detector 3 Audio Push Pull and Rectifier.

I am doing what I call a Hybrid Retrofit using transistors in place of tubes to get things running and considering collecting tubes for a proper refurbish.

For a quick, & dirty & temporary loop try winding/taping around the glass of a window or sliding door; and for that matter any wood door.

Greetings Rinus and Jordan. Some years ago I saw a door on the back of which had been made a flat loop. The door could be swung on its hinges to orientate for nulls etc. Been meaning to try it but "The Minister of War would not be happy" Regards to all .Max vk2tti.

This gain is noiseless unlike an active amplifier. A Q of 100-200 is not difficult to attain in a home made loop. If you had a 1m square loop of around 7 turns with a 500pF air spaced tuning capacitor with a 1 turn coupling loop to the receiver you should tune MW OK. More turns for LW, if the turns are around 5mm or 1/4" apart then the Q will be good, bundling the turns will greatly increase their capacitance and reduce the HF end of the tuning range as well as reducing the sensitivity.
>>>>
>>>> There are Q meters available but they are a bit rare these days. A SDR receiver and a signal generator can be used, you find the two frequencies where the loop output is 3dB down, subtract to get the bandwidth then divide the mid frequency by the bandwidth to reveal the Q number. A very rough test is how sharp the tuning is- if you wished the tuning knob was a lot bigger or you had a reduction gear because the tuning is sharp then you have a highish Q!!

Hi Rinus,

I thought that I might add my two cents' worth.

I have experimented with air loops of varying size and configuration both inside and outside as well as ferrite rod antennas of varying configurations such as 580mM single rod, 200mM single rod and 3.5" FSL's.

For a first-time DX'er I would recommend a 200mM ferrite rod antenna using cheap Litz wire.? I say this because it is relatively easy and cheap to build, convenient to use and provides good performance for its size.? You can add shielding, rearrange the windings or use higher performance litz, easily at a later time.? As your experience and expertise blossom, you may consider making additional antennas but the 200 ferrite will provide a good start.

There is a wealth of information on ferrite rod antennas on the 'net - search "ferrite rod antenna construction".? Unless you can use identical parts in constructing an existing loop, there are so many variables that some experimentation is inevitable.? If you begin with the mindset that "I am going to have to do some experimentation", you will be better equipped to get the best out of your components. One trick that I use is to wind more turns than I think I will need and then take turns off until it tunes as I want (removing turns is a lot easier than trying to add them).

As for power outages - they are a blessing.? In my part of suburbia, the man made noise is horrific.? When the power goes out (not often enough - curse the efficient distribution company) a whole new world of RX opens up.? But then getting away from the noise is a good excuse for trips to the wilderness.? Another reason for a 200mM antenna - it is highly portable - even taking it to the park can sometimes get rid of a lot of man made noise.? Carrying a 4 foot square air loop to the park is great for aerobic fitness but not for convenience.

Looks like my two cents turned into two dollars.? No matter, whatever path you finish up taking, I hope you get a lot of pleasure and satisfaction,

Ray

Hi Alan
Thanks a lot again , that you take the effort to make things clear for me
I really appreciate it.
And i understand it, what you write.
But it brings up new questions...
Has the used wire also influence on the Q?

and is there a relationship or ratio between the size of the loop, how much windings, spacing, wire's used, capacitance
and the frequency area where the loop is designed for?
is there somewhere a diagram , where one can read :< for example>...
i want to make a loop for VLF
which size do i need, how many turns, which wire , how much capacitance?
is there a ratio?< is that the right word?>

Hi Rinus,
Tuned circuit Q is sometimes called the "Quality Factor", it's how sharply the circuit resonates. So if you had a loop resonant at 1MHz (1000KHz) and a Q of 50 it will have a "bandwidth" of? f/Q = 1000/50=20 KHz?between the tuning points where the output is at half the peak power (-3dB).

Q has a multiplying effect on received signals, a loop with a? working Q of 200 will deliver four times (+12dB) more signal than a working Q of 50. This gain is noiseless unlike an active amplifier. A Q of 100-200 is not difficult to attain in a home made loop. If you had a 1m square loop of around 7 turns with a 500pF air spaced tuning capacitor with a 1 turn coupling loop to the receiver you should tune MW OK. More turns for LW, if the turns are around 5mm or 1/4" apart then the Q will be good, bundling the turns will greatly increase their capacitance and reduce the HF end of the tuning range as well as reducing the sensitivity.

There are Q meters available but they are a bit rare these days. A SDR receiver and a signal generator can be used, you find the two frequencies where the loop output is 3dB

down, subtract to get the bandwidth then divide the mid frequency by the bandwidth?to reveal the Q?number.? A very rough test is how sharp the tuning is- if you wished the tuning knob was a lot bigger or you had a reduction gear because the tuning is sharp then you have a highish Q!!??

I would seriously suggest that you make your?gear portable so you can?experience the vast difference getting away from household wiring and appliances makes, there is a day and night difference!

As said a little transistor MW radio is a useful tool for detecting noise from wiring , bulbs, wall warts and many other appliances, you can quickly find the main noise generators. If you have battery powered gear then it might be worth just switching off all of the power for a few moments?to kill all of your own local noise and hear what happens.

Good DX,

Alan

I have been using a 3-ft square tuned loop for 150 to 440 kHz with great success for many years. This is a "pancake4; loop, wound in a single plane. The coil consists of 80 turns of 22 AWG stranded wire. It is woven tennis-racket style on a wooden cross with holes drilled every 1/4 inch. The coil and tuning capacitor rotate 360 degrees laterally and 90 degrees vertically in order to produce excellent nulls in any direction.

There are a few basic points you need to consider. The signal is picked up by the coil. The capacitor is just there to provide resonance to the circuit. The values of inductance and capacitance at a given frequency are inversely proportional. Therefore, the tuned circuit should have the highest L/C ratio possible in order to optimize pickup.

In order to minimize capacitance, some effort should be made to lower the distributed capacitance of the coil. The distributed capacitance is partially a function of the shape of the coil. Given the same inductance, a pancake coil (vs. a solenoid shape) will have the least distributed capacitance.

You can feed the coil/capacitor with a characteristic low impedance in series with the transmission line. This however will place the transmission line and receiver in series with the tuned circuit at resonance and effectively lower the Q. My loop is fed from a pickup coil (3 turns, 8-inch diameter) mounted in the center of the primary coil. The primary coil and pickup coil thus form a transformer. This allows the main coil and capacitor forming the tuned circuit to "freewheel" in space under minimal load, and preserves the high Q. In fact, Q is high enough that the circuit must be repeaked every kHz.

Dear Rinus,
Domestic noise is increasing indoors these days and if you want receiving indoors it will pick up the electric and magnetic noise component from switch regulator and alike.
If you want to suppress the domestic noise the best way is probably installing the ferrite loop above the roof noise level away from the source.
For indoor installing a ferrite loop antenne you can screen the loop for the electric field with a thin static wire screen not making short-circuit the RX field and so reduce the parasitic capacity and maintain the Q factor of the loop windings.
The noise from the electric field is reduced that way. Bud there is also noise in the magnetic component that may be reduced by turning the loop to de magnetic NUL from the source.
?
For an large air loop the windings should be screened also and that can be done with a RG214 coax loop and use the outer screen. On top it has a small open cap and not shorted the fields. The inner will be the loop itself and taken out from a small center gap below in the screen. The screen should below connect to ground.
A good description how to screen a ferrite loop can be found on this site from PA2OHH 60;?http://www.qsl.net/pa2ohh/07fer.htm handling this problem.
I have a professional Bendix ferrite loop antenne from an air craft automatic LW beacon direction finder with use also PA2OHH? his thin wire screening technique.

Topic: 11784 Message: 11784
Attachments: 2 described; binary payloads are missing from this source WARC

I have for sale two custom built 7.5" X 7.5" FSL antennas. The FSLs were wound in a 2 coil Polydorff configuration. The 2 windings were wound with 660/46 Litz wire and the variable capacitors are the Russian high Q, 2 gang, with a 3:1 turning ratio. I added a band switch so the second gang can be switched in for extended band coverage. Both FSL are mounted on a Lazy Susan base.

Band (1) tunes from 2,000 to 420 KHz and Band (2) tunes from 575 to 275 KHz. The tuning is sharp and the rotational nulls are quite sharp. Both FSLs are setup for induction coupling.

I am asking $325 each, plus what ever the shipping cost would be. Below is a pictures of one of the FSLs. If interested please contact me off list everettsharp@....

I have built and sold several FSLs, however, these two will be the last I build for sale, as I have used up all of my ferrite inventory. Most of the sources of supply for the Russian ferrite bars have dried up. Each of the FSLs have around $150 in material cost and about 20 hours work each. These are one of a kind and can not be bought anywhere else.

to ultralightdx

Hi Steven,

As you note, of course air is the lowest loss spacer but it's not very easy to wind a coil spaced over ferrite using just air. :) Styrofoam is probably the next least-lossy dielectric, and can often be found in sheets of varying thickness where a single layer or maybe several layers add up to the correct coil spacing. As for Litz, if you can obtain some, try to get as many strands of #46 gauge as your budget allows. I would suggest that a minimum of 100 strands of Litz be used (100/46) otherwise the improvement over using plain non-Litz wire won't be much. 175/46 and 330/46 are common sizes and are good choices, with 330/46 working better. And then there's the "Big Litz" such as 660/46 which works even better but which is much more expensive. Also remember the larger Litz is larger in diameter so make sure your coil form width can handle the extra winding width, and also that you will need somewhat more turns for the larger size Litz you use, to tune the same frequency range using the same variable capacitor since the inductance for a given number of turns will decrease the larger the wire diameter that is used.

Good luck and please keep us informed of your experiments and results! And it must be fun to listen to Radio Caroline live; you're fortunate to be able to receive the signal, even in daytime.

(Some of this is reposted from 2014 on this newsgroup)

For plastics used in RF, you're looking for the compounds with the lowest "loss tangent"/"dissipation factor" (which varies with frequency).

Teflon, polystyrene, polyethylene...

Pretty much anything but PVC!

If you can't buy decent capacitors made with it, it's no good for RF.

http://www.kayelaby.npl.co.uk/general_physics/2_6/2_6_5.html

See the last column. Compare PTFE to PVC.

http://www.dtic.mil/dtic/tr/fulltext/u2/746686.pdf has some lovely graphs.

Also, PVC for use in sunlight often has lead in the mix, although they are slowly phasing that out. It's not elemental lead, but still...

http://www.pvc.org/en/p/lead-stabilisers

As for sources of litz wire for LF work, consider scrapping some large quality SMPS's - they usually have inductors wound with it. Usually fairly meaty diameters. I'm not sure strand #'s, I've got a bucketful of them put aside for future LF use.

There is a simple and sensitive test for plastics that is very widely used. Put a small sample in a microwave oven along with a cup of cold water. Run the microwave for 5 seconds then touch the plastic. if it is warm then it is lossy, if cold then run with the cup of water for 60 seconds. If the plastic is warm then it is lossy at 2400MHz. Very sensitive test as losses at microwave frequency are very much greater than a few MHz..

In practice I doubt that ANY commercial PVC would contribute ANY significant loss at LF/MF, I would appreciate any factual data that Andy has on measured losses at say 1MHz in a Loop application. Although winding coils on plastic covered metal tubes is not a great idea. Don't laser PVC however! A lot of plastic plumbing is NOT PVC but Polypropylene.

Litz from switchers is made from a few strands of thick wire, not a great improvement over solid. Better litz has very many hair thin strands. Litz is not essential for rods or loops.

Haven't made any measurements yet. Have to dig the 8405A out of storage.

Considering we're trying to pull a signal out of the noise 5kHz way from a nearby powerhouse transmitter, high antenna Q is a great objective to strive for* - the "inverse garbage in garbage out" rule. High antenna Q comes from quality capacitors and inductors.

Spending big dollars on litz wire then winding it on a PVC former, you'd probably get better q from normal wire with air gap former while saving yourself a bunch of dollars.

* The "Q Multiplier + Spiral Loop Antenna (G Maynard design) I used to use with my Racal RA17L was so good, you could peak it on a portion of the sideband of the transmission you were listening to. The Q was so high, it required a capacitor with 3 reduction drives connected in series.

I understand the principles of Litz wire, and have used old antenna Litz
coils. Not being an engineer, I'm sure there are legitimate
applications. From a practical standpoint however, stranded hookup wire
has always worked well for me. (See below)
>

I reported similar results with my spiral (a.k.a. pancake) loop earlier
in this thread. 80 turns of 22 AWG stranded wire will produce a Q
necessitating retuning every kHz. In addition the large coil produces a
high effective height (mainly determined by the NA product (number of
turns times the area of each turn)).

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11791. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-02-01 04:12:37 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11791

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11792. Antique Radios

Hi
Looking for comment and advice.

A Senior Citizen SWL/Scanner Club and I are working on a retrofit/hybrid restore of some vintage Tube Radios.

We are looking into replacing the tubes with a low voltage, transistor, chip or PC Board amplifier.

We don't have working tubes. The intent is to prove out the rest of the components before going ahead to buy expensive vintage tubes.

A fringe benefit is eliminating the need for a big expensive multi voltage power supply.

There was a company called Skytek at one time selling solid state tube
replacements for Collins radios. These were called:
"tubesters". Another device was the Teledyne FETtron.

It was reported that use of these things severely degraded
the performance of the radio (except in the audio output
stage). Since you only want to prove out the rest of the components,
you might be able to get away with a cheap and dirty circuit
that you are not going to use in the long run. For the
AM broadcast band at ~1 MHz, you should be able to just
use op amps of 50 MHz GBW product to get the very high
input simulating a grid. Radios this old probably
used triodes with moderately high output impedance so
you can just put a large resistor in series with the
op amp output for that. Should act like a tube.

From: Will Kimber
Topic: 11792 Message: 11795

If you only want a quick test make your own fetron, j-Fet with video
(high voltage) transistor in cascode.

Should be a lot cheaper than tubes for permanent replacements if it works.

Cheers,
Will

11796. Pixel Pro-1B loop - Amplifier questions

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-02-19 17:37:13 UTC
From: singleshare@...
Topic: 11796 Message: 11796

I've had a Z1501F active antenna from Clifton Labs for a number of years now (RIP Jack). I also have the Z1203B Power Injector. The Antenna has been an excellent performer, however I've been in the mood to tinker a bit.

I've come across a nicely priced DXE-RFPRO1B-PA, which is the amplifier used for the Pixel Pro-1B. I'm also looking to buy the Loop Antenna (just the loop) that DXE seels for $149.00.

I figure I can just use the Z1203B power injector for the Pixel Pro amplifier. I'm curious though how similar the Pixel Pro amplifier might be to the Z1501F. I wonder if i can use them interchangeably? Loop on either, active whip on either?

Thanks for any thoughts.

Yes you can do what you are suggesting. I have that set up now. I have a Dowkey relay outside and switch back and forth between my loop and the Clifton E Probe whip.

Years ago, not long after buying my Pixel RF Pro-1a, Pixel introduced the Pro-1b with both an 'improved' pre-amp and loop. After forwarding pix of my pre-amp & loop, it was established that I had the 1b pre-amp and 1a loop - they offered me an updated loop for the same price you quoted - even offered to throw in a 12V power inserter, after warning me that the voltage would be below the pre-amps three terminal regulator's minimum required input voltage for 'proper' operation. The P-92 Power Inserter that came with my Pro-1a supplies +20V DC at up to 150 mA on the pre-amp's feed. A 12V DC inserter would have been welcome after the nearby tornado strike of 1/13, which killed my AC power for days after clearing my deck of everything except the apron mounted Pixel 'lollipop', which had wound up tight all the RG-6QS. When power was restored, it worked fine - but after the power company reset their poles and lines, I had RFI from three directions, so, after almost 36 years there, I moved to a garden home with a tall walkup attic - and a no outside antenna edict from the HOA. The Pixel loop is on a 5ft mast in a tripod base resting on the floored part of the attic and yields the clearest reception I've ever had - no doubt the underground utilities help. I don't miss my antenna farm... I even had ladder line feeding wire antennas, which included 150ft lw, TTFD, Slopers, dipoles, trap dipoles, and an E-probe. Many of my huge pines and oaks, including all tof my wire support trees, fell to weather or disease. The Pro-1a resurrected my SWL hobby - even more so after I moved.

Everett, I thought that the Pixel loop is relatively lo-Z - and it's amp is a lo-Z input - which the Clfton E-probe pre-amp isn't. How do you accommodate the difference? Does your Clifton amp work well on 12V? Are his amps (Z1501 ??) still available. Oh, I still use your LW loop! Thanks!

John

John,

I use the higher voltage for for both. The Pixel has a voltage regulator, so no problem. 50 ohms- 75 ohms no big deal. Jack Smith said it was okay to do it.

The Z1203B power coupler has an adjustable output from 9V - 24V.
http://cliftonlaboratories.com/z1203b_coupler.htm
http://cliftonlaboratories.com/z1203b_coupler.htm

The Z1501F variant of the active antenna uses 20V while the Z1501D uses 13.8V.

Since the Z1501F and Pro-1B both use 20V I like the idea of switching between the two.

DX Engineering aquired Clifton Labs. I guess it remains to be seen what products will be on the market.

Hi

Does anyone have any experience With the McKay Dymek Active Antenna
Control Box with other Active Antennas?

http://www.prc68.com/I/DR33.shtml#DA100

The DA-100 is an active whip antenna covering the LF through HF bands.
It's a very good disign even by today's standards for use in the LF area.
Although the schematic for the indoor power supply looks straight forward
the design of the AC transformer is very sophisticated in that it blocks
LF signals coming in on the power line. Something the AMRAD active whip
power supply did not do as well, but they made provision to run from a
battery.

---

http://www.ebay.co.uk/itm/Stoner-McKay-Dymek-DA-100D-Active-HF-Antenna-Power-Supply-Contro
l-Box-/192098695796?hash=item2cb9f97a74:g:YBIAAOSwmmxW33AM

Stoner McKay Dymek DA-100D Active Indoor/ Outdoor HF Antenna Power Supply
Control Box

Details:

-
*Active Indoor/ Outdoor HF Antenna Power Supply Control Box *
- This general coverage active offers great receive performance from 500
kHz to 30 MHz.
- The DA-100D can be run from 110-120 or 12 VDC (2.5 mm jack).
- A 110 VAC wall-type power supply is provided.
- Output impedance is selectable at 50, 100 or 500 ohms.
- A three position attenuator is also featured (0, -10 and -20 dB).
- The output jack to the receiver is an RCA phono jack.

Specifications:

Manufacturer:* Stoner McKay Dymek*
Part Number:* DA-100D*

Also Known As:
DA100D

I Have a Hula Hoop PC Board and a Russian Preamp to go with to go with four
foot diameter Magnetic Loops on the 8th floor balcony of a concrete and
steel building.

Varactor Voltage Filter?
Jordan Dobrikin <jjdobrikin@...>
to Anton
Hi
As I see it C9, R5, C1, & R1 is smoothing filter. Are they necessary if the variable voltage power supply is well filtered? Also is there an English version of the text?
73 de Jordan ve7jjd
to me Russian English Translate message Turn off for: Russian
Hello, Jordan.
Yes, it is filter. If you use long wires from power supply to preamp you need it. If you use short wire I think you can remove this filter. But I would keep it. Unfortunately only russian version, but you can write to the author DL2KQ, I think he knows English and can translate :)
Понедельник, 14 ноября 2016, 10:18 +08:00 от Jordan Dobrikin <jjdobrikin@...>:
Power receiving antenna
The differential amplifier for receiving the frame and ferrite antenna. For receiving loop antennas (such as "flags") requires an amplifier. With the noise and gain no problems. This is easy to do.
But such an antenna because of the small useful signal from the amplifier requires a very high attenuation coefficient of the in-phase component (CMRR CMRR or English from the Common-Mode Rejection Ratio), as otherwise made braided power cable spurious signals completely spoil the work of the antenna (which is often the case and is the source of the opinion that such antennas operate as himself).
The easiest way to implement it, making a differential amplifier with a large CMRR. And the need is power. Structural type of scheme balun + unbalanced power will not give a good result. Even the best such transformers, common mode rejection ratio of 1.8 and 3,6 MHz (and receiving antennas are needed mainly on the low bands) rarely exceeds 40 dB (talk about high impedance transformers). But that is not enough: a typical receiving antenna gain -30 dBi, its ratio F / B another 20 ... 30 dB, then we need a minimum of 50 ... 60 dB attenuation in-phase component.
Differential is such suppression may be amplifiers. But they need to be integrated. The idea to make difkaskad discrete transistors is divided on almost impossible to find a pair of transistors with an accuracy of 0.3 ... 0.1% (this is the same 50 ... 60 dB suppression, only expressed as a percentage).
Average performance of differential stage op amp provides a suppression, but it has to have the disadvantage that the input impedances of both inputs are obtained by different. From this dish loses its symmetry.
Decision fully satisfies us is the use of a specialized differential amplifier AD8129 . Below 4 MHz it has the CMRR higher than 80 (!) DB and two differential inputs with an equal and very high (> 4 MOhm) impedance.
AD8129 separate advantage is that the differential inputs are used to set the gain, i.e. they do not need to load anything extra.
Schematic of the amplifier circuit is shown in the following figure. Black elements on it are shown mounted in any case, the red - only when the

magnetic antenna with the ferrite, green - only when the frame.
The gain (in this case, it is equal to 30) is given by the ratio of voltage R7 / R6 resistors. These resistors have no effect on the input impedance on the working inputs (pins 1 and 8 chips DA1).
Power bipolar chips (note, in the scheme of two different ground). Filters L1-C2-C4 and L2-C3-C5 unleash the power (this is in addition to the CMR). The mid-point (ground amplifier) defines stabilizer DA2.
Power to the amplifier can be supplied by a common coaxial cable (as shown). For further isolation from the dirt on the outside of the braid mounted decoupling choke T2. He wound LF ferrite core, inductance> 1 mH. RF choke L4 divides the power and output RF signals.
If the power is supplied to the amplifier not coax, and on a separate line, L4 is not necessary, and T2 is two-winding. In this case, both windings T2 are wound in one direction (as in any power throttle) 12 and the voltage + V is applied to the second input through DA2 winding T2.
The output of the amplifier through R8 is connected to the separation of HF transformer T1, a low interturn capacitance and the winding ratio of 1: 1. This transformer is needed to isolate the common-mode signal between the amplifier ground and the braid of the coaxial drop cable. Resistor R8 coordinates transformer T1 (DA1 at the very low output impedance).
Protective diodes VD7 VD8 (any silicon high) to prevent overloading the receiver (DA1 may issue up to 5 V amplitude, which is not like all receivers). C7 separation.
L3 elements C10 shared shack in the power of the amplifier and the receiver input.
Inductors L3, L4 inductance of 200 uH and above.
But back to the door of the shack amplifier: terminals 1 and 8 DA1. As already mentioned, this high-impedance differential inputs with high (> 80 dB) CMRR. They need to solve three problems:
Snap DC. This is done by resistors R3, R4. Their face value is not very important (in addition to working with a ferrite magnetic antenna, see below.) From 100 k to 1 M. But desperately important that they are identical: they will have to pick up the digital tester with honors no more than 0.1% (preferably less). Otherwise, they skewed input of the amplifier, with a corresponding decrease in AUC.
Protect entrances at the transmitter. Couple VD5 RF diodes, VD6 to deal with it.
Connect the antenna and the necessary elements to it. It depends on which antenna will be used:
If apertodicheskaya frame, such as the "flag", it is connected directly to the inputs. Additionally, the resistor R2 is set with a resistance equal to the input frame (typically a few hundred ohms)
If this ferrite magnetic resonance antenna or 1 ... 2 Coiled frame, R2 is absent, and the restructuring are set varicap VD1 -VD4 (I used BB640) and management of the chain of the shack: R1, R5, C1, C9 . In addition, when working with a ferrite magnetic antenna (MA) is necessary to reflect on the nominal value of R3 and R4. It defines the quality factor of the antenna circuit (of course, in addition to single quality factor of the antenna coil). Depending on the inductance, single Q MA and the desired bandwidth

(no adjustment) and select ratings R3, R4.
The following figure shows the spectrum in the band 100 kHz at the output of the amplifier described with denominations R3 R4 390 k and attached ferrite magnetic antenna on the rod with a diameter of 400 μ = 8 mm and 100 mm in length. The range of 160 meters, the antenna is located inside the building, so in addition to the useful signals can be seen more and a lot of noise and the degree of attenuation:
The output level of terrestrial noise resonance MA is - 93 dBm (the vertical scale in the figure in dBm), ie 5 uV, which roughly corresponds to the level of noise with a full-sized antenna. If you need to change the gain, then it is done divider R7 / R6. AD8129 can provide a gain of up to 100 times on the low HF bands.
Of course, for normal reception, the antenna should be brought somewhere far away and higher up on local sources of interference.
Update on 01/14/2015. That review UK8AFV described in the amplifier. There have just above the circuit board.

From: Francis S
Topic: 11807 Message: 11807

Just spent most of the afternoon attempting to raise my 80 meter sky loop antenna. I had ropes slung over the trees at four points and measured out the almost 300 feet of wire. I thought it would be an "easy" task using those dog bone insulators at the attach points to run the wire thru from one to the other..... I thought the wire would ride inside the insulator and I could just pull the wire feeding one to the next.... boy, was I wrong! Was it friction or what..... the wire would not feed easily, I had to pay out maybe 30 feet and then pull it thru the next point and then back to the first one.... on and on and on. Perhaps there might be some other type of insulator available that would allow for the wire to float more easily, or I could get some help to make the job go faster! Just wondering what other guys have been using for this necessary piece of the construction.

Hello

The relative inflexibility of the wire going around corners is the problem. The metal probably "work hardens"
as it bends around each insulator and gets progressively harder as each new insulator is accessed.

I suspect all (well, 75% of it) of the wire will have to be pulled thru the first insulator, then half pulled thru the
2nd and then one quarter pulled thru the 3rd and the two ends joined
together at the 4th.

Good luck with your project . . .

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11812. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-01 04:19:34 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11812

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

Topic: 11813 Message: 11816

Hello Jordan,

You can give this link a try for the 01A. Just go to the thumbnails on the right-hand side of the page for schematic details.

http://www.greenhillsgf.com/Project_SS-Tubes.htm
http://www.greenhillsgf.com/Project_SS-Tubes.htm

Here's another article, using MOSFETs to directly replace triodes (e.g., the 226). Since you are working at lower voltages, your job might be even easier.

http://www.geofex.com/Article_Folders/mosfet_folly/mosfetfolly.htm
http://www.geofex.com/Article_Folders/mosfet_folly/mosfetfolly.htm

Lots of stuff on the Internet with respect to tube replacement using transistors, etc. If these links don't quite do it for you, then you can use some of the key words in these articles and your friend Google to find better sources.

I wish you good fortune in your search! mvm.

11818. Varicaps

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-10 01:50:12 UTC
From: gnuarm.2007@...
Topic: 11818 Message: 11818

I'm looking at building a low frequency VCXO with a variable cap diode to control the frequency. I'm having a hard time finding a source for a 240 or 120 kHz crystal, but sooner or later I'll find a manufacturer who will sample some parts.

I'm looking at the tuning diode. I've found a lot of web pages that talk about using standard diodes or LEDs or the BE junction of BJTs. A couple of them have measured data for the capacitance vs. voltage. For the voltage range I'll have (0 to 3.3v) most barely give you a 2:1 capacitance change. So I looked at some hyperabrupt junction tuning diodes. I can get units with 10:1 capacitance ratio over that voltage range! Digikey has them for under a dollar at qty 1. So why would anyone want to use a poor substitute rather than the "real" thing?

I'm not sure what range of cap I'll need really. I'm not trying to make a widely tunable oscillator. I want to be able to adjust it to stay on frequency as it drifts. So I need enough capacitance to bend the crystal frequency by maybe ±100 ppm or 20 Hz. I'm thinking with a crystal specified for 12.5 pF load capacitance, if I use two diodes, one on each end of the crystal, with a range of 5 to 50 pF, the crystal will see 2.5 to 25 (plus the stray capacitance). Any idea if that will be enough in both directions?

Rick C.

Breadboard the oscillator with a mechanical variable capacitor and measure the results. Go from there.

From: bob71741@...
Topic: 11818 Message: 11820

You will have better results pulling/phase locking the xtal at 2 MHz(or so) with the varactor and then dividing the output by 10 or so to get your 240 KHz.

You can also get a xtal with +/- 20 ppm stability with out temp control, if I remember correctly.

I am repeating a message i just read on EMRFD group mail.

International Crystal Manufacturing Company is closing.

This company has been in business for a long time, over the years
manufacturing kits, CB radios, and quartz crystals made to order.

As another noted: “End of an era”.

11822. Faraday Loop for Magnetic Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-13 04:51:49 UTC
From: hmholden69@...
Topic: 11822 Message: 11822

I'm building a magnetic loop antenna for shortwave reception. I have noticed in all the technical literature related to building the loop, that they say that the smaller feeder loop, usually some flavor of a faraday loop, should be 1/5 the circumference of the main loop. What is the reason for this? Does it have something to do with impedence matching or what.

11823. Re: Faraday Loop for Magnetic Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-13 05:06:44 UTC
From: gnuarm.2007@...
Topic: 11822 Message: 11823

I believe that is correct, the issue is impedance matching. But there are other ways to adapt the very low impedance of a magnetic loop to a receiver. One I have seen but not yet tried is to use a toroid core for the coupling. A small number of turns on the loop for the feeder and the main loop would pass through the torus once. An old PC power supply could be a good source for an appropriate core, but only for lower frequency signals.

Rick C.

11824. Re: [loopantennas] Re: Faraday Loop for Magnetic Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-13 06:53:58 UTC
From: Jordan Dobrikin
Topic: 11822 Message: 11824

There are 50 million ways to extract the signal from the big loop to the Receiver not all coils and nothing really to choose between them as they all are about equal. For HF with the loop outdoors I recommend a low noise wide band Preamp or a Preamp with Varactor Tuning Preamp.

I am curious as to the details of the Loop you are building.

Hi
Translation
73 de Jordan ve7jjd

http://dl2kq.de/ant/3-96.htm

нтон Г.
Hello, Jordan.
I translated the part of description this preamp from web-site DL2KQ. This is about you case
---
If this ferrite magnetic resonance antenna or 1 ... 2 Coiled loop, R2 is absent, and tuning are set varicap VD1 -VD4 (I used BB640) and their control circut of the shack: R1, R5, C1, C9. In addition, when working with a ferrite magnetic antenna (MA) is necessary think over the nominal value of R3 and R4. It defines Q factor the antenna circuit (of course, in addition to single Q of the antenna coil). Depending on the inductance, single Q MA and the desired bandwidth (no adjustment) and select ratings R3, R4.

When you use resonance antenna (magnetic loop for example) you need to turn it to different frequencies. That's why you need varicap.
The preamp works great from 0.1 to 10 MHz and works fine from 10 to 28 MHz.

Power receiving antenna
The differential amplifier for receiving the frame and ferrite antenna.
For receiving loop antennas (such as "flags") requires an amplifier. With the noise and gain no problems. This is easy to do.
But such an antenna because of the small useful signal from the amplifier requires a very high attenuation coefficient of the in-phase component (CMRR CMRR or English from the Common-Mode Rejection Ratio), as otherwise made braided power cable spurious signals completely spoil the work of the antenna (which is often the case and is the source of the opinion that such antennas operate as himself).
The easiest way to implement it, making a differential amplifier with a large CMRR. And the need is power. Structural type of scheme balun + unbalanced power will not give a good result. Even the best such transformers, common mode rejection ratio of 1.8 and 3,6 MHz (and receiving antennas are needed mainly on the low bands) rarely exceeds 40 dB (talk about high impedance transformers). But that is not enough: a typical receiving antenna gain -30 dBi, its ratio F / B another 20 ... 30 dB, then we need a minimum of 50 ... 60 dB attenuation in-phase component.
Differential is such suppression may be amplifiers. But they need to be

integrated. The idea to make difkaskad discrete transistors is divided on almost impossible to find a pair of transistors with an accuracy of 0.3 ... 0.1% (this is the same 50 ... 60 dB suppression, only expressed as a percentage).
Average performance of differential stage op amp provides a suppression, but it has to have the disadvantage that the input impedances of both inputs are obtained by different. From this dish loses its symmetry.
Decision fully satisfies us is the use of a specialized differential amplifier AD8129 . Below 4 MHz it has the CMRR higher than 80 (!) DB and two differential inputs with an equal and very high (> 4 MOhm) impedance.
AD8129 separate advantage is that the differential inputs are used to set the gain, i.e. they do not need to load anything extra.
Schematic of the amplifier circuit is shown in the following figure. Black elements on it are shown mounted in any case, the red - only when the magnetic antenna with the ferrite, green - only when the frame.
The gain (in this case, it is equal to 30) is given by the ratio of voltage R7 / R6 resistors. These resistors have no effect on the input impedance on the working inputs (pins 1 and 8 chips DA1).
Power bipolar chips (note, in the scheme of two different ground). Filters L1-C2-C4 and L2-C3-C5 unleash the power (this is in addition to the CMR).
The mid-point (ground amplifier) defines stabilizer DA2.
Power to the amplifier can be supplied by a common coaxial cable (as shown). For further isolation from the dirt on the outside of the braid mounted decoupling choke T2. He wound LF ferrite core, inductance> 1 mH. RF choke L4 divides the power and output RF signals.
If the power is supplied to the amplifier not coax, and on a separate line, L4 is not necessary, and T2 is two-winding. In this case, both windings T2 are wound in one direction (as in any power throttle) 12 and the voltage + V is applied to the second input through DA2 winding T2.
The output of the amplifier through R8 is connected to the separation of HF transformer T1, a low interturn capacitance and the winding ratio of 1: 1.
This transformer is needed to isolate the common-mode signal between the amplifier ground and the braid of the coaxial drop cable. Resistor R8 coordinates transformer T1 (DA1 at the very low output impedance).
Protective diodes VD7 VD8 (any silicon high) to prevent overloading the receiver (DA1 may issue up to 5 V amplitude, which is not like all receivers). C7 separation.
L3 elements C10 shared shack in the power of the amplifier and the receiver input.
Inductors L3, L4 inductance of 200 uH and above.
But back to the door of the shack amplifier: terminals 1 and 8 DA1. As already mentioned, this high-impedance differential inputs with high (> 80 dB) CMRR. They need to solve three problems:
Snap DC. This is done by resistors R3, R4. Their face value is not very important (in addition to working with a ferrite magnetic antenna, see below.) From 100 k to 1 M. But desperately important that they are identical: they will have to pick up the digital tester with honors no more than 0.1% (preferably less). Otherwise, they skewed input of the amplifier, with a corresponding decrease in AUC.

Protect entrances at the transmitter. Couple VD5 RF diodes, VD6 to deal with it.
Connect the antenna and the necessary elements to it. It depends on which antenna will be used:
If apertodicheskaya frame, such as the "flag", it is connected directly to the inputs. Additionally, the resistor R2 is set with a resistance equal to the input frame (typically a few hundred ohms)
If this ferrite magnetic resonance antenna or 1 ... 2 Coiled frame, R2 is absent, and the restructuring are set varicap VD1 -VD4 (I used BB640) and management of the chain of the shack: R1, R5, C1, C9 . In addition, when working with a ferrite magnetic antenna (MA) is necessary to reflect on the nominal value of R3 and R4. It defines the quality factor of the antenna circuit (of course, in addition to single quality factor of the antenna coil). Depending on the inductance, single Q MA and the desired bandwidth (no adjustment) and select ratings R3, R4.
The following figure shows the spectrum in the band 100 kHz at the output of the amplifier described with denominations R3 R4 390 k and attached ferrite magnetic antenna on the rod with a diameter of 400 μ = 8 mm and 100 mm in length. The range of 160 meters, the antenna is located inside the building, so in addition to the useful signals can be seen more and a lot of noise and the degree of attenuation:
The output level of terrestrial noise resonance MA is - 93 dBm (the vertical scale in the figure in dBm), ie 5 uV, which roughly corresponds to the level of noise with a full-sized antenna. If you need to change the gain, then it is done divider R7 / R6. AD8129 can provide a gain of up to 100 times on the low HF bands.
Of course, for normal reception, the antenna should be brought somewhere far away and higher up on local sources of interference.
Update on 01/14/2015. That review UK8AFV described in the amplifier. There have just above the circuit board.

11826. New to Loop antennas

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-13 12:20:15 UTC
From: gstern48@...
Topic: 11826 Message: 11826

I am new to Loop antennas. I bought Chameleon CHA P-Loop antenna from DX Engineers. On sale for $300. I am not using the antenna for QRP, but as a back up antenna for my bedroom Icom R-75 receiver and maybe for my SDR-PLAY as a panadapter on HF. My wife will not think it's good looking in bedroom. HA HA!

We are in the low Solar Cycle. 20 meters is terrible and 40 is better in the late evening, but I am not getting a good SSB signal on R-75 with Loop antenna in my bedroom. I adjusted the loop tuner adjustment (very easy) to the highest signal strength on R-75 and position the antenna in many directions, but no legible SSB HF signal. I have a BHI DSP speaker to take out white noise. Loop Magnetic antennas are suppose to be much quieter than Dipole and Vertical antennas. Please give me some helpful tips?

Sincerely,
Gene KC4FA

The 1/5 is the ratio of the main loop parallel resistance and the cable resistance, typically 50 ohms, power 0.25. The parallel resistance is in the order of tenth of Kohms.
There are several coupling methods, it is a question of taste. My loop is "canonical" 1m diameter copper tubing 16 mm and I don't need preamplifier. I tested coupling loop and threaded toroids with 6 turns on the cable side. The ferrite tested are mix 31 and 47 (very popular). 31 is lossy on low bands (>60m), 47 on high (<17m). Coupling loop perform very close to mix 31.
The following links can help to make a good choice. https://www.nonstopsystems.com/radio/pdf-ant/article-antenna-mag-loop-2.pdf http://www.lz1aq.signacor.com/docs/fa-eng/Weak_signals-mag_loop_engl.htm

11828. Litz wire

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-14 18:56:25 UTC
From: david.sarraf@...
Topic: 11828 Message: 11828

The use of litz wire is a frequent discussion topic in this group. Discussions on litz wire construction are rare. I've uploaded a paper, "Simplified Design Method for Litz Wire", that provides a method for designing litz wire in the context of transformers and inductors for switching power supplies. The value of the paper to this group can be found in equations 1 and 4 and the latter half of section V1, Experimental Measurements. In particular, equation 4 provides a simple way to evaluate the suitability of of a particular litz wire construction based on frequency (skin depth) and strand construction.

Hi
Get the antenna far away from the ambient noise that plagues today's modern households.
Out doors is best; at a window next best; if you have an attic that minimizes the amount of solids the signals must penetrate.
As Air Conditioning in your car and Remote Control on your TV are no longer a luxury, but a necessity so goes a Rotator; IMHO.

Consider adapting low cost HDTV Antenna/Rotator found on Ebay

11832. Magnetic Loop on the Signal Hound Spectrum Analyzer

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-18 18:26:27 UTC
From: alexander.the.hard@...
Topic: 11832 Message: 11832

Magnetic Loop on the Signal Hound Spectrum Analyzer

On Saturday 18 March, COMMSPREPPER published his first video on the Chameleon P-LOOP 2.0. In that video COMMSPREPPER uses the Signal Hound to sweep the Chameleon P-LOOP 2.0 across the 40 meters band. The sweep was quite impressive, showing a very tight bandwidth, indicating a very high Q, as well as a very low and consistent SWR across the band.

11833. Indoor Horizontal Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-22 04:03:11 UTC
From: bfarina@...
Topic: 11833 Message: 11833

I have a small apartment and I'd like to build an indoor antenna for my SDR. The room that I'd like to install it in is approximately 9x8. What I'm thinking of doing is building a loop or loops of single strand cat-5 wire.

I have a number of questions:

Can I loop the wire, attaching both ends to the center conductor or should I go from center conductor to shield?

Can I create a second loop and attach it to the shield wire, or should I run that wire to ground?

If I run the shield to ground, is it safe to use the ground connector of a 3 prong, 110 wall outlet?

From some of the diagrams that I've seen, it looks like I can 'Y' multiple lengths of wire off the same center conductor (or the female stinger connection) to allow the reception of multiple bands. True?

I realize that some of these questions conflict a bit, but I'm having a little trouble searching for diagrams that specifically relate to my circumstances.

Second thought, Will you tune the loop with a variable capacitor?
Or will
you use the loop/s untuned?
What
female connector is on your SDR, SMA, BNC or SO239?
Do you
use a stand alone SDR or connect it to a laptop or descktop computer?
Regards
Max vk2tti.

11837. Re: Indoor Horizontal Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-26 10:58:53 UTC
From: deridog@...
Topic: 11833 Message: 11837

Power grid earth is usually a source of RFI.
There are many ways to couple the loop to the coax.
I understand your loop is indoor and receiving only, so the best choice is a preamplifier with hi input impedance. There are many schemes on the web.
The coupling loop is wide band, but not efficient as the preamp. Usually it is 1/5 diameter of the main loop. Another method is passing the antenna loop through a ferrite ring The secondary side of the transformer is then formed by several turns of insulated or enameled wire.

Hi,

You are going to pick up an awful lot of noise from any indoor antenna, but you might have no other choice.
Do an on-line search for "carpet loop antenna". There was an article by David Moisan N1KGH that gave wiring diagrams and everything else you could ask for. It was written back in 2003, and his loop went under the floor-coverings, but all the principles are the same.

Try the basic loop, first, and let us know how you get on.

Best Wishes
David, GM8XBZ

Can I loop the wire, attaching both ends to the center conductor or should I go from center conductor to shield?

Can I create a second loop and attach it to the shield wire, or should I run that wire to ground?

If I run the shield to ground, is it safe to use the ground connector of a 3 prong, 110 wall outlet?

From some of the diagrams that I've seen, it looks like I can 'Y' multiple lengths of wire off the same center conductor (or the female stinger connection) to allow the reception of multiple bands. True?

I realize that some of these questions conflict a bit, but I'm having a little trouble searching for diagrams that specifically relate to my circumstances.

Third point: Loops are balanced antennas - they don't need to be earthed.

(Unless they're shielded loops - in which case the shield should ideally be earthed at the antenna, but in practice 90% of the time they end up earthed at the receiver end.)

And yeah, the mains earth is not RF earth.

Hi

toddemslie@... [ultralightdx] <ultralightdx@yahoogroups.com>
3:05 PM (1 hour ago)
to ultralightdx

Yes Chuck, Gordon Nelson's 4' NRC loop featured very high tuning Q, although it also included a specially constructed amplifier to isolate the main tank coil. The electronics is the reason why the 4' NRC loop was so selective. Take away the isolation amp, in terms of selectivity, it is just a garden variety 4' loop. The tilting feature was useful for nulling local signals.
A high Q FSL portable antenna can be used to slope detect DX by peaking the loop's response to one side of an unwanted strong domestic signal. One example is trying to receive 567 KHz Wellington, New Zealand adjacent to local 50 kW 576 KHz ABC Sydney. By tuning a high Q loop to approximately 560 KHz, the signal from 576 KHz is reduced, hence less adjacent channel splash to 567 KHz. This is especially useful at the low of the MW band.

Certain variations of Litz wire feature lower resistance, hence higher Q. Although the trade-off is somewhat muffled audio response at the low end of the band. To partly get around this, slope detection tuning offset slightly away from the wanted DX signal is beneficial as outlined above. A possible analog to this is the IF passband tuning control on the Drake receivers.

G'day Bill F, Sounds like you are having The Mother of all Battles with Noise so you are looking at a Faraday Shielded Loop where one end of the shield goes nowhere but the cable is bent round into a loop and its centre conductor is connected to the shield near the SMA connector end at the radio.
It will be hard to join this all to an SMA Plug, it's so small. Perhaps a BNC plug would be easier to work with and use an BNC female / SMA male connector. I am not familiar with Cat5 cables, presumeably it has a centre conductor and a braided shield.
Get a male BNC RG58 crimp connector, prepare one end of the cable by soldering the centre conductor to the pin of the BNC connector and bare the shield and work the pin and shield into their proper place.
Go to the other end of the cable slipping the crimp sleeve over the cable end and down to the BNC connector, DO NOT CRIMP YET.
Go back to the end opposite the BNC connector, trim that end so you have about 3/8 inch of centre conductor sticking out, trim back the braid about 1/8 inches so it cannot connect to anything now or later.
Bring the end with the bared conductor around to the BNC end.
Push the bared conductor in amongst the strands of the braid under the crimp ring and crimp that ring, braid and conductor together to the back of the BNC male.
You now have a Farady Shielded Loop with a BNC connector at one end and the centre connector only of the other end earthed at the BNC end.

I have found much noise rides on the ac mains. I use a powerline filter between the wall outlet and my electronic gear with some success.

There is no magic bullet for the noise problem, all one can do is nibble away at the problem bit by bit.

Regards Max vk2tti

11843. Re: [loopantennas] Indoor Horizontal Loop Antenna

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-27 03:43:06 UTC
From: Will Kimber
Topic: 11833 Message: 11843

Cat5 is basically telephone cable. O.K its actually ethernet 100MHz twin twisted pair and this is solid not stranded conductors. Not shielded.

I'm having trouble understanding what the OP really wants to do. A large loop like this normally needs a tuner to make transition to co-ax that would go to SDR.

He could connect one end of loop (all conductors shorted together and connect that to center of co-ax. That is a random long wire a/e. He could make it into a loop by joining other end of loop to co-ax shield and take his luck on its resonant frequency.

Cheers,

Will

Thanks Will, I though cat5 was twisted pair but I am usually wrong, could be shielded cat5 is available, it's a big world out there. I also was not sure that I understood Bill F. thats why all the questions. He certainly will have a noise problem at his QTH. I don't think cat5 will be a solution. However a single strand of cat5 wire one end to the pin of the SMA connector and the other end to the shell of the SMA connector would form a large horizontal omnidirectional unshielded loop. Not immune to noise. Max vk2tti.

11845. Indoor Horizontal Loop Antenna - Results So Far

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-03-27 19:58:49 UTC
From: Bill Farina
Topic: 11833 Message: 11845

Everyone,
Thank you for all the input, It's been extremely helpful.
What I have done so far is take a single strand from a Cat5 cable. Cat5 is low bandwidth computer network cable. It has 8 single strands or 4pr wound inside a plastic shield. I have a ton of scraps laying around since I do network infrastructure for a living. What I did is take one of those strands and looped it around the inside of a room using about 35'. I connected one end to the center conductor of a short SMA jumper and connected the other end to the shield of that same jumper.
I originally had a short telescoping antenna attached to the back of the radio. I live in a valley in the mountains and this gave me some reception for local business and govt transmissions.
My intention is to try to receive some shortwave signals.

Currently the noise level that I'm getting is fairly low. It's comparable to the telescoping antenna. I just completed hooking everything up and I'm starting to scan the bands to see what I can pick up that I wasn't able to pick up originally. I'm not sure how much effort I want to put into this antenna because I'm probably only here for the next 6 months. Planning to bounce down to the Florida coast in the near future.

Cheers,
BillKE0WPF

G'day Bill F, Sounds like you are having The Mother of all Battles with Noise so you are looking at a Faraday Shielded Loop where one end of the shield goes nowhere but the cable is bent round into a loop and its centre conductor is connected to the shield near the SMA connector end at the radio.
It will be hard to join this all to an SMA Plug, it's so small. Perhaps a BNC plug would be easier to work with and use an BNC female / SMA male connector. I am not familiar with Cat5 cables, presumeably it has a centre conductor and a braided shield.
Get a male BNC RG58 crimp connector, prepare one end of the cable by soldering the centre conductor to the pin of the BNC connector and bare the shield and work the pin and shield into their proper place.
Go to the other end of the cable slipping the crimp sleeve over the cable end and down to the BNC connector, DO NOT CRIMP YET.
Go back to the end opposite the BNC connector, trim that end so you have about 3/8 inch of centre conductor sticking out, trim back the braid about 1/8 inches so it cannot connect to anything now or later.
Bring the end with the bared conductor around to the BNC end.
Push the bared conductor in amongst the strands of the braid under the crimp ring and crimp that ring, braid and conductor together to the back of the BNC male.
You now have a Farady Shielded Loop with a BNC connector at one end and the centre

connector only of the other end earthed at the BNC end.

I have found much noise rides on the ac mains. I use a powerline filter between the wall outlet and my electronic gear with some success.

There is no magic bullet for the noise problem, all one can do is nibble away at the problem bit by bit.

Regards Max vk2tti

Subject:Re: [loopantennas] Indoor Horizontal Loop Antenna

Second thought, Will you tune the loop with a variable capacitor? No
Or will you use the loop/s untuned? Yes
What female connector is on your SDR, SMA, BNC or SO239? SMA
Do you use a stand alone SDR or connect it to a laptop or descktop computer? Connected to desktop.
Regards Max vk2tti.

Subject:[loopantennas] Indoor Horizontal Loop Antenna

I have a small apartment and I'd like to build an indoor antenna for my SDR. The room that I'd like to install it in is approximately 9x8. What I'm thinking of doing is building a loop or loops of single strand cat-5 wire.

I have a number of questions:

Can I loop the wire, attaching both ends to the center conductor or should I go from center conductor to shield?

Can I create a second loop and attach it to the shield wire, or should I run that wire to ground?

If I run the shield to ground, is it safe to use the ground connector of a 3 prong, 110 wall outlet?

From some of the diagrams that I've seen, it looks like I can 'Y' multiple lengths of wire off the same center conductor (or the female stinger connection) to allow the reception of multiple bands. True?

I realize that some of these questions conflict a bit, but I'm having a little trouble searching for diagrams that specifically relate to my circumstances.

Greetings Bill F., Am glad we have been helpful. Sounds like you move around a bit. Might I suggest the longest ferrite rod, or short rods butted together with glue, and wound with a length single cat5 wire. Small, portable used tuned (series tuned) or untuned (with a preselector). The top of a local mountain using the SDR and laptop might be a productive day out. Enjoy, best wishes, Max vk2tti.

Not that it matters for reception -- but you could have used the complete CAT5 cable, with all strands paralleled. One-eighth the resistance, one-eighth the IR loss. For receiving, it might not matter enough to be noticed, but for transmitting it would.

Loops work best when balanced. neither wire going to earth ground. That tends to make them less sensitive to noise pickup.

Andy

Bill, You can attach a loop antenna to your SDR and a laptop running on its battery. One end of the untuned loop wire going to the centre pin of the SMA and the other end of the wire to the "earthy" , "shield" side of the SMA connector. NOTHING IN THIS SETUP IS CONNECTED TO THE DIRT OF THE EARTH. It will still work as normal. A mobile phone is just a radio, you hold it in your hand 5 feet above the earth and it still works, there seems to some confusion beatween the types of earths, dirt, RF earths and earths for electric mains safety. A loop and a dipole work in outer space, nowhere near the earth. You are receiving advice in dribs and drabs confusing the issue. Foresake the internet, get a basic book on loop antennas such as ones by Joe Carr and carry on from there. Regards Max vk2tti.

> and attach nothing to the shield of the SMA?
>

No. Because then you wouldn't have a loop! You would have a wad of wire attached to the center conductor.

The loop has two terminals. The feedline has two terminals. They need to connect together like that, terminal-to-terminal, in order to work.

Ideally, the loop antenna system would be balanced, not unbalanced (one side "grounded"). You might achieve that by using a "balun" between the unbalanced coax and the (otherwise) balanced loop.

I don't want to imply that you have to actually do this. It may be that everything is good enough without doing that. But ideally, it would make your loop antenna balanced, and then it would reject common-mode noise. Most local electrical noise sources induce common-mode voltages onto the antenna. If those kinds of noise sources are not seriously affecting your antenna, then going to the effort of adding a balun, might not help much.

The balun would also remove the feedline coax as "part of the antenna system." Without it, both the loop and the coax are picking up radio signals, and to some degree they both add to become what goes into your radio. That might be thought of as good, but it's actually undesirable because the coax feedline might run close to equipment and power wires, and might pick up more noise which the loop antenna itself is not receiving.

It can be messy trying to figure out where all the signals go, so most of us don't try.

I guess I'm saying that there are further steps that MIGHT make things better, or they might not really help, and you can't always tell unless you try. If you are satisfied with the results now, then there's little need to "improve" it.

Andy

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)
- - - discontinued

* Terk AM Advantage Loop Antenna (Passive)
- - - http://www.terk.com/pdfs/Advantage.pdf

* RadioShack AM Loop Antanna # 15-1853 (Passive)
- - - Discontinued (Find 'used' on eBay)

* MTM Scientific AM Radio Loop Antenna (Passive)
* http://www.mtmscientific.com/loop.html
- - - Starter Kit, Deluxe Kit or Finished Antenna!

* * * Home made 'Box' AM Loop Antennas
- Usually 20" to 24" in size
- - Generally a simple Passive antenna
- - - Can be made Active with an add-on amplifier

#1. * Justice AM Loop Antenna (Active)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

Long LoopStick Antenna for MW DXing
Wound on a Three (3) Foot Length of PVC pipe, the "Long LoopStick Antenna" was an experiment to try to improve AM radio reception without using a long wire or ground.
http://ourworld.compuserve.com/homepages/Bill_Bowden/page2.htm

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11853. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-04-01 06:33:38 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11853

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.

Interesting that MTM appears to have discontinued the MW loop that Paul mentions, though links to old ads for it are still at the bottom of the page, though with "sorry, not available" all through the ads. Since it was an approx. 17 inch square loop, it certainly had a lot more capture area than the other commercial small tuned loops. And the review by radiojayallen is always worth reading.

73,

Steve

When considering AM Loop Antennas . . .
- - - It all comes down to Time? & Money?

How much Time? Are you going to be 'using' the Loop Antenna for DXing or simply for "Better" AM Radio Reception (Sports/Talk Radio Loop).

How Much Money? Are you willing to spend for a Loop Antenna to get the kind of better reception you want.

TBL: Time and Money translates to the AM Loop Antenna's Value to You.

The average radio listener (97%), who wants better AM Radio Reception, can spend $100 or less and get an AM Loop Antenna that meets their needs.

Here is a brief list of the more common AM Loop Antennas for $100 or less.

* Twin Coil Ferrite AM Loop Antenna (Active)
- - - http://www.ccrane.com/antennas/am-antennas/

* Torus Tuner 27" Loop Antenna (Passive)
- - - discontinued

* Select-A-Tenna Model #541M (Passive)

#1.a. Kiwa MW Air Loop Antenna

#1.b. Quantum Loop Antennas

. . . #3. Palomar Loop Antenna

Basic Wire Back Yard Loop Antennas
Full-wave loops are very popular antennas. They are especially useful on 80 and 40 meters where they perform well at modest heights. These are closed loops that are one full wavelength long. Horizontal loops may be fed at any convenient spot. For best performance, make your horizontal loop into a square, especially if it is to be used on several bands.

TL Loop Receiving Antenna 10 KHz - 30 MHz
The principle of operation is that an rf voltage appears across the terminals of a loop when it is placed in an electromagnetic field. The voltage is proportional to frequency for a given field strength and so at Very Low Frequencies the voltage is very small and requires greater amplification but it is not quite as simple as that. The new TL Loop uses a unique feedback system to optimise the amplification/noise factor over a much wider range than has been possible hitherto.

11870. File - UploadingFilesLinksPhotos.txt

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-05-01 06:17:55 UTC
From: loopantennas@yahoogroups.com
Topic: 457 Message: 11870

If you have a link relevant to the group, please post it in the Links section. If you just put it in a message, it will get lost in the shuffle after a few days. The coverage of the list is pretty broad.

All members can upload Links, Files, and Photos.

A few guidelines:

Try to place them in the proper folder, if it exists. If not, you can either just put it in the root folder and eventually I'll move it into the proper place, or create a folder.

When creating a folder or uploading a file or photo, please don't use spaces or punctuation. You can either use caps for the first letter of each word, or use underscore as a space.

Like this: "4x8Loop" or "4x8_loop" or "Steves_4x8_Loop"

Not like this: "Steve's 4 x 8 Loop." That goes for Folder names and File names.

A special note about the Photos section: Please crop in to the important parts. For photos, JPG saves smaller and looks better, for line drawings GIF is smaller and looks better. Please do not use TIFF/TIF or BMP files, the file size is way too big and I may delete without notice.

Feel free to ask if you need help figuring out how to crop and resample. Irfanview is a fairly easy to use program that loads just about any file, you can crop and resample from there: http://www.irfanview.com

Or for more complex stuff, another free program is GIMP: http://www.gimp.org

Attachments are now allowed, but please use judiciously. Rather than going out with the messages, they will be stored on the list but you'll get a link with the message.

A last note: if you see something in any folder or in the messages that looks like spam or simply inappropriate, don't post on the list- email me directly and tell me about it and I'll take care of it with a minimum of fuss.
loopantennas-owner@yahoogroups.com

Thanks,
Steve Greenfield

11871. Stacked Toroid Ferrite Loop with Palomar Amp

What does International Crystal do for Hams that other crystal makers don't? What special things do Hams need other than specific frequencies? If there is demand they will make the crystals. If there isn't adequate demand the only companies making those frequencies will go out of business.

Rick C.

11875. Does the ideal loop exist?

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-05-18 09:48:13 UTC
From: f8dql@...
Topic: 11875 Message: 11875

Hello,
I am living in a very noisy electromagnetic environnement, with lot of QRN/QRM.
I would like to set up a loop antenna only for reception, TX will be done on another antenna.

So I'm looking for a model that would be adjustable remotely, ideally through the coax cable.

Do you have any recommendations, commercial or not?

11876. durable designs to carry around in motorhome

Yahoo group: loopantennas (2013 — 2017)
Date: 2017-05-18 16:09:54 UTC
From: evofxdwg@...
Topic: 11876 Message: 11876

Recently retired Electrical Engineer and new forum member here. (not an active ham). I would like links or tips on durable loop designs i can carry around in a bay of my motorhome and deploy outside, possibly on top or on a pole or tree, on a picnic table, hang from a rope over a branch, etc., to the extent practical. I just got a Tecsun PL-880 to play with. I realize i will have to come up with, or copy, a (possibly active) coupling method as the loop may be remote from the radio. The tuner would have to be protected as well. I will initially be interested in the AM band.

2 ideas:
1. Bend thinwall PVC pipe in a circle (using heat gun or whatever method - I currently have not experimented with minimum bend radius!) Carefully thread a few loops of wire thru it, including a coupling loop. Cut/split a T fitting in half for installation at the joint, route wires thru unused T coupling, and glue together. Spacing & position of wires in loop is uncontrolled (I vaugely think from fields/physics that this doesnt matter for a magnetic antenna - confirm?) I have found one construction article that uses multi-conductor data cable for a loop by cutting and splicing appropriate colors. I belive I can thread a single wire multiple times thru a 1/2" pipe though. The T provides the possiblity of waterproof if a sealed base is constructed using an inexpensive NEMA waterproof box and glued to it

2. If cant bend PVC thinwall to small enough circle, construct PVC housing as above but straight sections with 90 degree couplers (no need to bend PVC), in a square or diamond. A variation might use 8 45 degree couplers which should be easier to thread wire thru.

3. Build a traditional multi-turn loop with spreaders, but cover the wires along thier plane with heavy tape or rigid plastic sheeting for durability protection.

Comments? Construction plans? With a Tecsun PL-880, will the loop provide much in the way of improving "listenability" out in the country? In the city? Im inclined to build a loop antenna just to see.

11877. Re: durable designs to carry around in motorhome

From: alienrelics@...
Topic: 11876 Message: 11877

I made a shielded loop by taking some computer ribbon cable, rolling it into a tube, and inserting it through a piece of flexible copper tubing. Then I curled the tubing into a circle. I then offset the ends of the cable and soldered together.

You can select the inductance with a rotary switch, if needed. Rather than soldering, you could use two IDC connectors of each gender. Simply peel one wire off the edge of each on opposite sides, and offset one ribbon cable before clamping down the IDC. Don't offset both!

This was for a BFO metal detector, so I needed it to be VERY stable. I had previously tried wood and plastic forms (covered with shielding tape), and found they drifted terribly. Move from shade to sun or back and it was unusable.

With the copper tube, it was rock solid. Of course, you can only ground one end of the copper tube.

From: gnuarm.2007@...
Topic: 11876 Message: 11878

Details of building a loop antenna for reception will vary according to your specific needs. The one comment I would make is that a loop antenna will require a rotator. Unless you lay the loop horizontal it is directional much like a dipole.

You might consider using coax. That is already waterproof (or can be) and can be used to make a shielded loop of any size and as many turns as you would like. RG-6 has an 18 gauge center conductor giving a low resistance across a range of frequencies. Pick your total cable length for the loop and buy two coax cable, each half that length. Connect just the center conductor in the middle (not the shield) and the other ends become your feed point. There are many ways to couple to this loop, and easy one is to use a ferrite core.

Rick C.

Hi The quintessentially 64/64,000 Dollar question.
There are commercial Receive Only Loops from Wellbrok Pixel and others but they are based on wide band low noise Pre-Amps, no adjustable Tuning.

For MW the C.Crane Twin Coil Antenna out doors on a Rotator works well. One could convert to HF by using a multi coil Ferrite Loop Stick from a Shortwave Portable Radio,there are some available on Ebay from a high end Russian Portable.

For HF one can use a DIY Loop and a Varactor tuned wide band low noise Pre Amp. Also available on ebay ; search antenna Hula Hoop.

I have a Russian built Preamp with a revised schematic to add Varactor tuning. http://www.ebay.com/itm/Flag-Pennant-LOOP-HF-Antenna-KIT-HAM-RADIO-SWL-50-Ohm-with-Preamp-/201553084711?hash=item2eed800127:g:Sb8AAOSwJ4hY-dzb http://www.ebay.com/itm/Flag-Pennant-LOOP-HF-Antenna-KIT-HAM-RADIO-SWL-50-Ohm-with-Preamp-/201553084711?hash=item2eed800127:g:Sb8AAOSwJ4hY-dzb

Both Preamps are powered thru the Coaxial cable.
73 de Jordan ve7jjd
http://dl2kq.de/ant/3-96.htm Varactor Voltage Filter? Jordan Dobrikin <jjdobrikin@gmail.com> to Anton Hi As I see it C9, R5, C1, & R1 is smoothing filter. Are they necessary if the variable voltage power supply is well filtered? Also is there an English version of the text? 73 de Jordan ve7jjd to me Russian English Translate message Turn off for: Russian Hello, Jordan. Yes, it is filter. If you use long wires from power supply to preamp you need it. If you use short wire I think you can remove this filter. But I would keep it. Unfortunately only russian version, but you can write to the author DL2KQ, I think he knows English and can translate :) Понедельник, 14 ноября 2016, 10:18 +08:00 от Jordan Dobrikin <jjdobrikin@gmail.com>: Power receiving antenna The differential amplifier for receiving the frame and ferrite antenna. For receiving loop antennas (such as "flags") requires an amplifier. With the noise and gain no problems. This is easy to do. But such an antenna because of the small useful signal from the amplifier requires a very high attenuation coefficient of the in-phase component (CMRR CMRR or English from the Common-Mode Rejection Ratio), as otherwise made braided power cable spurious signals completely spoil the work of the antenna (which is often the case and is the source of the opinion that such antennas operate as himself). The easiest way to implement it, making a differential amplifier with a large CMRR. And the need is power. Structural type of scheme balun + unbalanced power will not give a good result. Even the best such transformers, common mode rejection ratio of 1.8 and 3,6 MHz (and receiving antennas are needed mainly on the low bands) rarely exceeds 40 dB (talk about high impedance transformers). But that is not enough: a typical receiving antenna gain -30 dBi, its ratio F / B another 20 ... 30 dB, then we need a minimum of 50 ... 60 dB attenuation in-phase component. Differential is such suppression may be amplifiers. But they need to be integrated. The idea to make difkaskad discrete transistors is divided on almost impossible to find a pair of transistors with an accuracy of 0.3 ... 0.1% (this is the same 50 ... 60 dB suppression, only expressed as a percentage). Average performance of differential stage op amp provides a suppression, but it has to have the disadvantage that the input impedances of both inputs are obtained by different. From this dish loses its symmetry. Decision fully satisfies us is the use of a specialized differential amplifier AD8129 . Below 4 MHz it has the CMRR higher than 80 (!) DB and two differential inputs with an equal and very high (> 4 MOhm) impedance. AD8129 separate advantage is that the differential inputs are used to set the gain, i.e. they do not need to load anything extra. Schematic of the amplifier circuit is shown in the following figure. Black elements on it are shown mounted in any case, the red - only when the magnetic antenna with the ferrite, green - only when the frame. The gain (in this case, it is equal

to 30) is given by the ratio of voltage R7 / R6 resistors. These resistors have no effect on the input impedance on the working inputs (pins 1 and 8 chips DA1). Power bipolar chips (note, in the scheme of two different ground). Filters L1-C2-C4 and L2-C3-C5 unleash the power (this is in addition to the CMR). The mid-point (ground amplifier) defines stabilizer DA2. Power to the amplifier can be supplied by a common coaxial cable (as shown). For further isolation from the dirt on the outside of the braid mounted decoupling choke T2. He wound LF ferrite core, inductance> 1 mH. RF choke L4 divides the power and output RF signals. If the power is supplied to the amplifier not coax, and on a separate line, L4 is not necessary, and T2 is two-winding. In this case, both windings T2 are wound in one direction (as in any power throttle) 12 and the voltage + V is applied to the second input through DA2 winding T2. The output of the amplifier through R8 is connected to the separation of HF transformer T1, a low interturn capacitance and the winding ratio of 1: 1. This transformer is needed to isolate the common-mode signal between the amplifier ground and the braid of the coaxial drop cable. Resistor R8 coordinates transformer T1 (DA1 at the very low output impedance). Protective diodes VD7 VD8 (any silicon high) to prevent overloading the receiver (DA1 may issue up to 5 V amplitude, which is not like all receivers). C7 separation. L3 elements C10 shared shack in the power of the amplifier and the receiver input. Inductors L3, L4 inductance of 200 uH and above. But back to the door of the shack amplifier: terminals 1 and 8 DA1. As already mentioned, this high-impedance differential inputs with high (> 80 dB) CMRR. They need to solve three problems: Snap DC. This is done by resistors R3, R4. Their face value is not very important (in addition to working with a ferrite magnetic antenna, see below.) From 100 k to 1 M. But desperately important that they are identical: they will have to pick up the digital tester with honors no more than 0.1% (preferably less). Otherwise, they skewed input of the amplifier, with a corresponding decrease in AUC. Protect entrances at the transmitter. Couple VD5 RF diodes, VD6 to deal with it. Connect the antenna and the necessary elements to it. It depends on which antenna will be used: If apertodicheskaya frame, such as the "flag", it is connected directly to the inputs. Additionally, the resistor R2 is set with a resistance equal to the input frame (typically a few hundred ohms) If this ferrite magnetic resonance antenna or 1 ... 2 Coiled frame, R2 is absent, and the restructuring are set varicap VD1 -VD4 (I used BB640) and management of the chain of the shack: R1, R5, C1, C9 . In addition, when working with a ferrite magnetic antenna (MA) is necessary to reflect on the nominal value of R3 and R4. It defines the quality factor of the antenna circuit (of course, in addition to single quality factor of the antenna coil). Depending on the inductance, single Q MA and the desired bandwidth (no adjustment) and select ratings R3, R4. The following figure shows the spectrum in the band 100 kHz at the output of the amplifier described with denominations R3 R4 390 k and attached ferrite magnetic antenna on the rod with a diameter of 400 μ = 8 mm and 100 mm in length. The range of 160 meters, the antenna is located inside the building, so in addition to the useful signals can be seen more and a lot of noise and the degree of attenuation: The output level of terrestrial noise resonance MA is - 93 dBm (the vertical scale in the figure in dBm), ie 5 uV, which roughly corresponds to the level of noise with a full-sized antenna. If you need to change the gain, then it is done divider R7 / R6. AD8129 can provide a gain of up to 100 times on the low HF bands. Of course, for normal reception, the antenna should be brought somewhere far away and higher up on local sources of interference. Update on 01/14/2015. That review UK8AFV described in the amplifier. There have just above the circuit board. Beer Sheva, 26.09.2014

Hi
For Medium Wave I suggest a C.Crane/Justice Twin Coil Antenna, (Ferrite Loop Stick), mounted piggy back on a Low cost HDTV Antenna/Rotator both available on ebay with good prices.

For an "Electrically Small", Air Loop, plain wire, 1 to 2 turns roughly one tenth of a Wave Length, as large an Area as possible, driving a Low Noise Wide Band Preamplifier.

For Loops the name of the game is Low Inductance, large surface Area Rotatable. The various copper pipe, Coax, etc. are for transmitting, with Receiving coming along for the ride.

For a "Full Size Air Loop hanging from a tree/pole we are back to a Low Noise, Wide Band Preamplifier.

Low Noise Wide Band Preamplifier and Varactor Tuning option.

Power receiving antenna
The differential amplifier for receiving the frame and ferrite antenna.
For receiving loop antennas (such as "flags") requires an amplifier. With the noise and gain no problems. This is easy to do.
But such an antenna because of the small useful signal from the amplifier requires a very high attenuation coefficient of the in-phase component (CMRR CMRR or English from the Common-Mode Rejection Ratio), as otherwise made braided power cable spurious signals completely spoil the work of the antenna (which is often the case and is the source of the opinion that such antennas operate as himself).
The easiest way to implement it, making a differential amplifier with a large CMRR. And the need is power. Structural type of scheme balun + unbalanced power will not give a good result. Even the best such transformers, common mode rejection ratio of 1.8 and 3,6 MHz (and receiving antennas are needed mainly on the low bands) rarely exceeds 40 dB (talk about high impedance transformers). But that is not enough: a typical receiving antenna gain -30 dBi, its ratio F / B another 20 ... 30 dB, then we need a minimum of 50 ... 60 dB attenuation in-phase component.
Differential is such suppression may be amplifiers. But they need to be integrated. The idea to make difkaskad discrete transistors is divided on

almost impossible to find a pair of transistors with an accuracy of 0.3 ... 0.1% (this is the same 50 ... 60 dB suppression, only expressed as a percentage).
Average performance of differential stage op amp provides a suppression, but it has to have the disadvantage that the input impedances of both inputs are obtained by different. From this dish loses its symmetry.
Decision fully satisfies us is the use of a specialized differential amplifier AD8129 . Below 4 MHz it has the CMRR higher than 80 (!) DB and two differential inputs with an equal and very high (> 4 MOhm) impedance.
AD8129 separate advantage is that the differential inputs are used to set the gain, i.e. they do not need to load anything extra.
Schematic of the amplifier circuit is shown in the following figure. Black elements on it are shown mounted in any case, the red - only when the magnetic antenna with the ferrite, green - only when the frame.
The gain (in this case, it is equal to 30) is given by the ratio of voltage R7 / R6 resistors. These resistors have no effect on the input impedance on the working inputs (pins 1 and 8 chips DA1).
Power bipolar chips (note, in the scheme of two different ground). Filters L1-C2-C4 and L2-C3-C5 unleash the power (this is in addition to the CMR).
The mid-point (ground amplifier) defines stabilizer DA2.
Power to the amplifier can be supplied by a common coaxial cable (as shown). For further isolation from the dirt on the outside of the braid mounted decoupling choke T2. He wound LF ferrite core, inductance> 1 mH. RF choke L4 divides the power and output RF signals.
If the power is supplied to the amplifier not coax, and on a separate line, L4 is not necessary, and T2 is two-winding. In this case, both windings T2 are wound in one direction (as in any power throttle) 12 and the voltage + V is applied to the second input through DA2 winding T2.
The output of the amplifier through R8 is connected to the separation of HF transformer T1, a low interturn capacitance and the winding ratio of 1: 1.
This transformer is needed to isolate the common-mode signal between the amplifier ground and the braid of the coaxial drop cable. Resistor R8 coordinates transformer T1 (DA1 at the very low output impedance).
Protective diodes VD7 VD8 (any silicon high) to prevent overloading the receiver (DA1 may issue up to 5 V amplitude, which is not like all receivers). C7 separation.
L3 elements C10 shared shack in the power of the amplifier and the receiver input.
Inductors L3, L4 inductance of 200 uH and above.
But back to the door of the shack amplifier: terminals 1 and 8 DA1. As already mentioned, this high-impedance differential inputs with high (> 80 dB) CMRR. They need to solve three problems:
Snap DC. This is done by resistors R3, R4. Their face value is not very important (in addition to working with a ferrite magnetic antenna, see below.) From 100 k to 1 M. But desperately important that they are identical: they will have to pick up the digital tester with honors no more than 0.1% (preferably less). Otherwise, they skewed input of the amplifier, with a corresponding decrease in AUC.
Protect entrances at the transmitter. Couple VD5 RF diodes, VD6 to deal

with it.
Connect the antenna and the necessary elements to it. It depends on which antenna will be used:
If apertodicheskaya frame, such as the "flag", it is connected directly to the inputs. Additionally, the resistor R2 is set with a resistance equal to the input frame (typically a few hundred ohms)
If this ferrite magnetic resonance antenna or 1 ... 2 Coiled frame, R2 is absent, and the restructuring are set varicap VD1 -VD4 (I used BB640) and management of the chain of the shack: R1, R5, C1, C9 . In addition, when working with a ferrite magnetic antenna (MA) is necessary to reflect on the nominal value of R3 and R4. It defines the quality factor of the antenna circuit (of course, in addition to single quality factor of the antenna coil). Depending on the inductance, single Q MA and the desired bandwidth (no adjustment) and select ratings R3, R4.
The following figure shows the spectrum in the band 100 kHz at the output of the amplifier described with denominations R3 R4 390 k and attached ferrite magnetic antenna on the rod with a diameter of 400 μ = 8 mm and 100 mm in length. The range of 160 meters, the antenna is located inside the building, so in addition to the useful signals can be seen more and a lot of noise and the degree of attenuation:
The output level of terrestrial noise resonance MA is - 93 dBm (the vertical scale in the figure in dBm), ie 5 uV, which roughly corresponds to the level of noise with a full-sized antenna. If you need to change the gain, then it is done divider R7 / R6. AD8129 can provide a gain of up to 100 times on the low HF bands.
Of course, for normal reception, the antenna should be brought somewhere far away and higher up on local sources of interference.
Update on 01/14/2015. That review UK8AFV described in the amplifier. There have just above the circuit board.

What is a loop and why use it?
1). A loop antenna is a small multi turn loop of less than 1/10th wavelength in length. The loop is wound on a form, which may be either box (solenoid), or spiral (pancake) wound. The core material can either be air, or a powdered iron compound (Ferrite). The gain of a loop is much less than a longwire, but it has much less noise pickup. A properly designed Loop primarily responds to the magnetic component of the radio wave. Note that noise resides primarily in the electrical component. A vertical antenna responds mainly to the electrical component.

Principles of the Loop Antenna
A loop antenna is an antenna primarily for the AM broadcast and the Longwave bands. There are two different types of loop antennas, one is the ferrite bar (as in your am radio), the other is wound on an air core form.
A loop antenna is very directional. The pickup pattern is shaped like a figure eight. The loop will allow signals on opposite sides to be received, while off the sides of the loop the signal will decrease or be nulled out. The nulling feature will allow you to remove a local station on a frequency and pick up another on the same frequency by removing the local signal.
A loop may have an amplifier or may not.
Air core loop antennas come in many sizes. The larger the loop the more gain there is. A small loop will actually lose part of the signal. That is why most small loops will use an amplifier. There are two ways a loop can be wound, box or spiral. In the box or solenoid loop the plane of the winding are wound perpendicular to the diameter of the loop, so each loop is the same size. In the spiral loop the plane of the windings are wound parallel with the diameter of the loop, so each loop gets smaller as you wind into the center of the loop. A loop needs to be able to rotate to null out a station. And a loop also needs to be able to tilt from vertical. This also helps in in nulling of a signal (altazimuth feature).
The number of turns the loop needs is determined by the size of the loop, the frequency range that you want to tune and the value of your tuning capacitor. The larger the loop the fewer turns you will need. A 4 foot loop needs 8 turns and a 2 foot loop needs 18 turns. The capacitor that is used is the standard AM tuning capacitor with a range of 10 to 365 pf. The tuning capacitor is used to tune the loop to the frequency that you want to listen to. When you are tuned in to the frequency the signal will peak. You may not be able to tune the full frequency range that you want to tune. So you will need to use a 2 section capacitor and switch the second section in. (more capacitance).
There are three ways that you can connect your loop to your radio.
One way is not connecting it at all. (This requires a portable radio with a internal loop antenna.) The field of the loop will radiate the peaked signal and you will be able to pick it up with no connection to the radio. You can move the radio around to get the best reception.
You can also direct couple to the loop. This way you connect to each end of the loop and also to the center tap of the loop. Using this method you will need to use it with an amplifier.
The last method is to use a pick up coil. This consists of one turn of wire that is placed inside the loop on the cross arms. This is then connected to the radio. The distance from the main tank coil can be determined by using a pocket radio and moving it inside the loop to find the place were the signal is strongest, and were it peaks sharpest.

In the past loops were made from wood. I have built them and found them to be heavy, clumsy, and flimsy. The mounting system were not very stable. In talking with Mike Bates, he came up with the idea of using PVC to build loops. PVC is easy to cut and because you use PVC molded parts, the loop that you make are is stable. By using PVC cement for some gluing and small nylon screws to connect parts you have no metal parts except the wire and tuning cap to throw the pattern of the loop off. Using PVC it helps to have a drill press, but if a person drills very carefully there should be little problems.
What is a loop and why use it?
1). A loop antenna is a small multi turn loop of less than 1/10th wavelength in length. The loop is wound on a form, which may be either box (solenoid), or spiral (pancake) wound. The core material can either be air, or a powdered iron compound (Ferrite). The gain of a loop is much less than a longwire, but it has much less noise pickup. A properly designed Loop primarily responds to the magnetic component of the radio wave. Note that noise resides primarily in the electrical component. A vertical antenna responds mainly to the electrical component.
2). Why use a loop?
A). No available space for a longwire antenna
B). To eliminate unwanted signals, and noise
C). Radio Direction Finding
D). To improve the performance of a simple receiving system, by providing pre-selection which improves image rejection, and adjacent channel selectivity.

3). History
A) 1915-1920’s Early receivers used loop antennas, until they were discontinued in favor of long wire antennas, prior to 1930.
The loop antenna appeared again about 1938. This time it was used to eliminate the need for a longwire antenna, and to provide for safer operation of the small midget AC/DC sets that came into wide use at that time.
B). The first known use of a high performance loop antenna is the box loop made by Ray Moore in the mid 1940’s(1) This antenna was written up in DX Horizons in 1960. The Moore Loop was wound on a 40" square box frame. Note: Ray Moore is the Author of the book on the history of Communications Receivers, and a new companion book on Transmitters.
C). The next major advance in Loop Antenna design came about as a result of advances by Gordon Nelson of the National Radio Club. The NRC Loop Antenna(2)was designed by Nelson in the Mid to Late 1960’s time frame, Nelson was at M.I.T. at the time. The major advance that Nelson made was allowing the loop to rotate in the vertical as well as horizontal plane. The addition of the Alt-azimuth adjustment allows for the elimination of the effects of "wave tilt" and allows for much deeper nulling of certain stations. This loop was a 35" on a side and wound on a wood frame. In one form it utilized another Nelson first, a direct coupled Balanced amplifier using 2N4416 J-FET’s with the outputs fed to a balanced feedline. The other version was link coupled to the receiver.
D). Sanserino Loop (1970-1985) This is a 2 foot Air core box loop designed

by Ralph Sanserino, and later marketed by Radio West. This loop antenna used a Differential Amplifier similar to Nelson’s except the output is not balanced. This antenna also has the Alt-azimuth feature. (available as a kit) The amplifier was later used in the Radio West Ferrite Loop Antenna (see below) .
E). Joe Worchester (1970-1977) a retired GE engineer developed the "Space Magnet ", a small 12" ferrite rod loop antenna using a Bipolar Junction Transistor amplifier(3). Nulls were not as deep as with the Nelson Loop. This is also probably the first loop antenna commercially available to the hobbyist, at a cost of about $45.00 if I remember correctly. Later versions utilized the Nelson Alt-azimuth feature. This antenna also used a Faraday Shield around the Ferrite Bar.
F). Mackay Dymek (1974-Early 1980’s) , Palomar Engineers (1977-current). These are small ferrite antennas made by larger commercial concerns. The Mackay Dymek was primarily for the Broadcast Band, where the Palomar has plug in coils for ranges from 10Khz to 15Mhz. Note that both of these antennas incorporated alt-azimuth design.
G). Radio West(1979-1985) 23" ferrite rod assembly using Sanserino Differential Amplifier, direct coupled, Has Alt-azimuth feature, $160.00 in 1979.High performance for its day, quieter than the "Space Magnet"
H). Quantum Loop (about 1990) by Gerry Thomas is a small ferrite rod less than 1’ in size (length), with a high gain 40Db amplifier. has Alt-azimuth feature, in current production in various forms $135-$200.00.
I). KIWA Loop 1992 First Air core available since Nelson/Sanserino. Uses IC amplifier Opto isolated regeneration and varactor tuning. High performance, solidly built, in current production. $360.00.
J). RSM Communications (Ray Moore) RSM-105 (1994) A high performance transformer coupled, non amplified antenna described by Moore in Dec 1994 IRCA DX Monitor, Later in March 6 1995 issue of NRC DX News. Still in production? Price?? 35" spiral wound.
4). Electrical Design Characteristics
A). Two main types of Loops available 1). Directly Coupled and 2). Indirectly coupled (Transformer coupled) The Directly Coupled Loop has its windings directly attached to an Amplifier. Usually the main Tank Coil (parallel tuned circuit that forms the loop primary) in the loop is grounded at the center of the winding (center tapped), to allow for electrical balancing. The Amplifiers are usually but not always J-FET’s, with 2 FET’s in a Differential configuration, where the ends of the tank winding go to each FET gate. The Transformer coupled version uses a link winding to couple the signal to the receiver. This version can be amplified or non amplified.
B). The pick up pattern of a properly designed loop should be a figure 8 pattern. The null should be of the same depth, if the antenna is rotated 180 degrees horizontally (loop should not be adjusted for alt-azimuth, but left vertical 90 degrees from the ground). The 180 degree symmetry should be the same + or - one degree. If this condition does not occur the Antenna is not properly balanced. In a transformer loop balance deals with the signals being equal on both lines of the feed line (equal potential to ground). The feed line should preferably be shielded with the shield being grounded to the receiver chassis. If the line is affected by an electric

field signal, a metallic object, or some other imbalance to ground, the loop will become unbalanced, resulting in a distortion of its pick up pattern. Balance is critical to getting the best nulls, and for precision Radio Direction Finding. The use of a broadband balun allows for better balance, but thought should be put into the design of the link winding, and receiver feed line, as well as the mechanical integrity of the coil.
C) The transformer coupled loop is the easiest to balance, especially if it is an air core loop. Ferrite loops are not as easy to balance due to the compression of flux lines in the ferrite. These antennas seem to be somewhat more prone to pick up electric fields.
D). In a directly coupled loop, the balance is affected by the gain of the amplifying devices on either side of the center tap being equal. If they are not very close to, or equal, they will cause the voltage in the tank coil to be imbalanced with respect to ground causing the same undesirable effects that the feed line caused in a Transformer Loop.
E). Some loops utilize a Faraday shield to maintain balance (4) Usually a one turn loop. these are usually circular, and are used on ships and other areas where direction finding is necessary. An example of this antenna is the 160 meter loop wound out of coax described by Doug DeMaw (5) Using a Faraday Shield will affect the pick up gain, as well as the "Q" of the tank coil(3) Another variant of the shielded loop is the Mike Hawk Loop(6)
Also note that imbalance is sometimes referred to as "Antenna Effect"(4)
Also please note that a balanced loop antenna can be spoiled to a cardioid pattern by putting a vertical sense antenna within its field.(4)
F). The amount of coupling (placement of the link turn) is critical to the performance of the Transformer Coupled Loop. The placement can vary depending upon the load that the antenna sees. The best way to obtain optimum performance is to experiment with various distances from the Tank Coil. Most designs call for this to be wound amongst the tank coil windings, however this coupling is much too tight for most uses, and allows for tuning to be too broad, Q to be too low, and sensitivity to be not quite optimal.
G). The physical size of the Loop Tank Coil affects the overall pickup (capture ability) of the loop. The larger the winding size the greater the pickup. Larger loops will also be easier to balance than smaller ones.
H). The Tuning Sharpness "Q" is determined by the size of the wire (surface area). The lower the resistance the higher the "Q" will be. The loading of the Tank Coil also affects the "Q". This more than wire resistance affects the Transformer Coupled Loop. In a Transformer Loop, the placement of the Link Coil in relation to the main tank (distance) determines the amount of coupling, and hence the loading of the tank circuit. The point of critical coupling can be found by varying the coupling link distance, while comparing tuning sharpness and gain. the critical coupling point will be found at the sharpest tuning before the gain starts to drop. Tuning will continue to sharpen (slightly), but gain will fall off more rapidly, as one couples more loosely (moving the link physically farther from the Tank Coil). Further improvement can be had by matching the load impedance to the link coil with a matching transformer. This can be done as part of a balun, or following the balun (lead-in side). For optimum performance all impedance’s in the system should be properly matched.

I). The L/C ratio and mechanical design of the coil should be considered when looking at a good design for a loop. The loop should be mechanically stable (wires not flopping loose) The distributed capacitance between turns should be kept low by proper design to allow for wide tuning range, but not too wide to degrade the length to diameter ratio of the coil. Note that the best null performance occurs with the best length to diameter ratio of the Tank Coil. A spiral wound coil affords the best performance in this regard, but does not afford as great a signal pickup as a solenoid coil of the same diameter. (A Trade off)
Also note that the L/C ratio should allow for one 10 to 500pf variable capacitor to tune the whole Medium Wave Broadcast Band.(530-1700 KC)
J). Performance can be further enhanced if the amplifier following a transformer coupled loop is tuned. This provides still better image rejection, and adjacent channel selectivity. It is important that the amplifier be isolated from the loop by a transformer to maintain balance and pattern integrity.
K). Note that the spacing of the windings determines the inter-electrode capacitance. The wider the spacing between windings, the lower the capacitance, and the higher in frequency the loop will tune. the use of interlaced spreaders further reduces this effect (solenoid loop) provided that the spreaders are of sufficient width. Also note that the winding spacing is a compromise with the length to diameter ratio.
Construction Principles
5). Mechanical design
A). Up to now, loops were made from wood. It was used because it was readily available and easy to work with. Wood does have disadvantages. They are, finding good wood, making accurate cuts, and heavy weight.
B). In a wood loop, the alt-azimuth tilting mechanism does not work very well. Wood loops use a bolt for the alt-azimuth tilt. It uses an arm that goes from the loop to a clamping setup on the mounting post. This does not work very well, as you need to tighten the bolt every time that you change the vertical tilt. The bolt will become loose, and on high angle tilts does not hold very well.
C). Most loops use a pipe mounted vertically with a dowel to do the horizontal rotation. This does not work well, as it allows the loop to move on it own. Wood will also wear after some use. This allows the loop to lose its square ness which can affect the loops pick up pattern.
D). The first loop I built was the Harley Loop(7). It is small spiral loop that was easy to build, but had no Alt-Azimuth feature, so the loop would not vertically tilt. It uses two cross arms with saw kerfs part way through to hold the wire.
E). I then built the 4 foot NRC Loop(2). This loop worked well, but the Alt-azimuth tilt needed work so I did some modification on the tilt mechanism. I wanted to design a tilt that would be easy to tilt and would stay in place. I tried different ideas and in my design I used a 3 inch PVC pipe for the mast and the loop head would tilt off that, this did work better but was not perfect.
F). While talking to Mike Bates(1995) about loops, He had the idea to build a large spiral octagon loop(5ft), out of PVC pipe and Alt-azimuth tilt it with a tripod. We built the loop, and this got my interest in using PVC for

designing and building loop antennas. The tripod did not work very well due to the heavy weight of the loop head, but the performance was quite good.
G). My next design was a 4 foot PVC spiral loop that is collapsible. New features added to this loop was the use of a lazy susan for the horizontal rotation of the loop, however, you need to use a liberal amount of grease to give it tension. For alt-azimuth tilt I took a 3/4 inch PVC tee, reamed out the inside smooth, and cut a slit length wise. Through this I ran a piece of PVC pipe and with the use of elbows and tees attached it to the loop head. I then used plastic hose clamps to adjust the tension. This worked better, but still did not work very well. It is hard to get the angle just right, it does not move smooth enough.
H). Then I built a 4 foot Loop modeled from the NRC plans(2) out of PVC. For this loop I added the use of PVC in the base. I used the same type of Alt-azimuth tilt mechanism as the earlier spiral. To mount it to the loop head, I used a hole in the crossover of the loop to attach to the alt-azimuth mount. This was done to allow for having the ability to build different loop heads, like one for the longwave beacon band. This allowed the loop head to rotate on the mounting mechanism which made the loop unstable, and not very easy to use. I decided to make the mounting like the spiral loop, but to add the tees, I needed to cut part of the tee to mount it on the loop arms. When I assembled it for fit, I found out that cut out tees worked much better for tilting, and hose clamps are no longer needed. The alt-azimuth tilt mechanism now works very smooth and holds well at all angles.
I). The 2 foot loop was also built based on the NRC plans(8), it employs a gimbal mount for alt-azimuth tilt.
J). These loops are made entirely out of PVC except for the base plate that employs a lazy susan to rotate the loop. I built jigs to drill the holes in the cross pieces. A drill press helps a lot, but with very careful measuring and drilling, a hand drill may work. In my first loops I used PVC cement to glue the loops together. This cement sets up very fast, so you have to be very careful assembling it. I found out that some parts can be glued, but on some it is better to use a small nylon screw. This allows for you to align the pieces right on. To do this drill and tap a hole for the screw and run it though both pieces of plastic (PVC).
K). It helps to make a jig to wind the tank coil onto the frame. To accomplish this I mounted a Lazy Susan to a board, and ran a board with two vertical pieces of PVC Pipe The loop frame slides over the pipes, allowing the loop to be rotated while the wire is brought off of the spool in the same direction, while being laced through the holes in the frame. This helps greatly, in minimizing twisting of the wire.
L). Reasons for using PVC in loop construction:
1). Readily available, at low cost
2). Easy to work with, Saw and drill are main tools required, however, a miter box saw allows for clean perpendicular cuts.
3) Very symmetrical loops can be built, because the fittings are identical, and pre made.
4). Very low weight
5). The ability to come up with modular designs 6). The ability to design a collapsible loop that can be mechanically strong, allowing for easy

transport
7). The use of spacers will tighten up the wires, so that they do not flop around, and distort the pickup pattern, as well as reduce inter-electrode capacitance. This makes for a very stable loop.
M). Notes:
Loop shapes: Triangle (Wedge), Square (Also called box, this is the most common shape) Octagon, Circular.
Note that the box loop is used because it is the simplest to build. The circular loop provides the nearest to the perfect shape electrically, but it is very difficult to fabricate a multi turn loop of this type. The octagonal loop is the practical compromise. Also note that the Octagonal is more difficult to fabricate due to it having 8 arms instead of 4, for the box loop.
What Can I use a Loop For
6). Using the Loop practical applications
The small loop is a versatile antenna, and can be used for many different applications, here are a few.
A). The loop can be used for improving the performance of a poorly designed broadcast receiver. Depending on the type of antenna that is in the receiver determines how the loop can be attached. It may be attached via a transmission line if the set has wire or screw binding posts for the Antenna, or it may be inductively coupled (transformer) for a receiver using a very small loop. In the case of the receiver with a small loop the coupling rules apply as if the receivers loop is the link turn in the Transformer loop. (Note that the link coil is not needed for the loop to work for this, as the internal loop in the receiver is receiving the signal from the main tank circuit). The distance from the receiver to the larger loop will determine the amount of coupling, and tank loading. One can vary the pick up pattern by varying the angle of the receivers internal antenna to the external loop. The antennas provide maximum transfer of signal, and closest to a figure 8 pattern. when the pick up angle of the antennas is opposite parallel (90 degrees) (Beams of the antennas aimed at each other) Minimum pickup occurs at 180 degrees. The pattern can be spoiled to a cardioid (null in only one direction) by varying the angle. Please note that the pattern will probably be somewhat spoiled from a figure 8 at the maximum signal 90 degree points. Please note that there are 2 commercially available products designed to inductively couple to the receiver, and improve its signal. These are the "Select A Tenna", and the "Q Stick" by Radio Plus (Gerry Thomas). However a 2ft or larger loop provides for much better performance provided one properly adjusts the coupling. A Large loop (4 ft) can cause a poorly designed receiver to overload. Loosening the coupling will allow for the overload to be eliminated. One must also be sure for proper operation that the loop is tuned to the same frequency that the loop is tuned to, or unwanted overload effects will likely be noted. All tuned circuits should be "aligned" to the same frequency. Also note that high Q tuned circuits can sometimes be touchy to adjust "spot on", some practice will probably be necessary. One can be amazed at the improvement in performance when using a properly designed loop. Stations can be brought from out of nowhere on a poor set. Images at the low end of the broadcast band will be cut down significantly or completely eliminated.

As stated previously, adding a properly designed tuned amplifier further improves the performance of the system. The amplifier can be fed by feedline to a coupling link that couples to the receivers internal loop, or can be direct attached to a receiver with antenna connections.
B). A loop when properly balanced can be used to "null down" AC Line noise, TV Sweep Harmonics, or other locally generated interference. The Alt-azimuth feature helps greatly reduce, sometimes totally eliminating the noise. This feature is also quite useful for nulling of co-channel, or adjacent channel broadcast band stations. If properly balanced, nulls of over 60 dB may be attained by using the Alt-azimuth feature. Deep nulls can be difficult to find and maintain. A larger antenna allows for one to find the null more easily due to the larger pick up(field) created by the loop. Loops of 2 ft and smaller in diameter, can be quite touchy to null, and electrical balance can be quite hard to attain. Hand capacitance can also affect the null in these small loops, causing the null to move as ones hand is moved away. This effect is minimized when using a large loop, as your whole body is within the pick up pattern of the loop, and it will be less likely to distort the pattern. One needs to be 6" to 1’ away from the small loop(2ft and smaller) to avoid the hand capacity effects. It is also notable that nulling works best on local ground wave signals. Distant sky wave signals can be more difficult to null. It is difficult to get a null of greater than 30 dB on a sky wave signal at the top end of the broadcast band at night. For Sky wave, phased antennas provide for much better nulling, but are much more complex, and difficult to operate. Also note that the higher the Q of the tank coil, the sharper the null. Sometimes the null will be excessively sharp, and difficult to find, or the null will be so narrow in bandwidth that the carrier of a station will be deeply nulled, but the sidebands will be well received as slop(splash). This affect is more noticeable in small, or amplified direct coupled loops.
C). Radio Direction Finding
One can accurately direction find signals provided that the antenna is properly balanced as described above. The general concept is that the deepest null will be in the direction of the signal being checked. You cannot use the Alt-azimuth feature, you must keep the loop perpendicular 90 degrees to the ground. An accurate compass, and a marked 360 degree circle can be used to pin point the exact bearing that the signal is coming from.

Bibliography from the three articles above can be found at the bottom of this page.

Loop Antennas Another Look
The last 30 years have brought about much refinement in the design of loop antennas. Starting from the basic box loop described by Ray Moore, major developments over this time are; The NRC 4ft Alt-azimuth loop, the Space Magnet, Sanserino Loop, Palomar, Mckay Dymek, Radio West, Quantum, Lankford, Kiwa, and RSM 105, and 103. As time has progressed, so has the design of Receiving Equipment, from the R390A, HQ-180, and SX-122 and Zenith Trans-Oceanic to the Sony 2010, Drake SW-8, Drake R8-B, and the AOR7030 Plus. Antenna needs have changed, with today’s broadband front ends, and synthesizer phase noise a concern, a high performance loop, or other means of pre-selection is more important than ever.

We will show a slightly different twist on the same basic loop antennas of the past, with a couple of refinements, as well as construction details of our antennas.

To explain our antennas we want to start with the design criteria necessary to improve the modern communications receiver, as well as consumer grade radios such as, the Super Radio III, the Radio Shack Optimus, and most other portable short wave/broadcast receivers.

Important loop criteria have been explained before in the pages of DX News, and the NRC Antenna Manuals, however, a review is in order. It is our opinion that there are 4 basic parameters that loop performance should be based upon; 1). The loops signal to noise ratio. 2). The electrical Balance. 3). The selectivity or "Q" of the loop. 4). The mechanical rigidity/integrity of the coil assembly, and Alt-azimuth mechanism.

Signal to Noise Ratio

Most efforts during the last 30 years have dealt with making loops smaller, to allow them to be used by the DXer who has limited space. S/N ratio has suffered as a result. The use of direct-coupled balanced FET amplifiers, and smaller, and smaller loop coils means that the bulk of the work in the system is being done by the amplifier. If you capture a very tiny signal, and add some amplifier noise to it, you have degraded what signal that you have to the point that you may bury a signal slightly above the noise floor. A rule of thumb would be to use no more amplification than is necessary. It is better to make the coil larger to enhance the capture area, and insure that what amplification is used is as low gain, and low noise as possible. The small loops are probably OK for most uses, but when you want to extract the last decibel out of the ether, a larger loop that is properly designed will be best.

Electrical Balance

The electrical balance of the antenna insures that the current at the termination of one end of the loop tank coil is of equal magnitude and opposite polarity to that at the other termination of the loop coil. (A is equal and opposite B) When properly balanced the deepest possible null will be obtained, with the loop. Please note that balance is quite difficult to attain. Anything connected to the tank coil (or other metal brought physically near it) other than the resonating capacitor, can throw this balance (equal and opposite) off. This distorts the theoretical figure 8 pattern of the loop. If a link turn is used to couple the loop to the receiver, this link and the transmission line must be balanced, or coupled to an unbalanced line (Coax Cable) using a Balun. The link coil should be balanced, as well as the main tank coil. Using a balanced FET amplifier on the tank coil will throw off the balance if care is not to insure that the FET’s are not exactly matched in their gain and transconductance. Not to mention that an amplifier not properly balanced, and running at excessive gain will be prone to create intermod products which degrade further the performance of the system. If a loop antenna seems to have a problem with hand capacitance it is a pretty good bet that it is not properly balanced. Refer to Nelson’s article for detailed hints on how to attain balance.

Selectivity

The "Q" or quality factor of the tank coil will determine its selectivity at resonance (the tuned frequency). If the "Q" of the tank coil is loaded

(reduced by the effect of a load on the coil), the "Q" will decrease, and the selectivity of the loop will decrease, or broaden. In the late 60’s Nelson devised the balanced FET amplifier as a way to minimize the loading of the tank coil. This allowed for selectivity that was so sharp that a loading potentiometer was added across the tank coil to reduce the "Q" so that the loop could be more easily tuned. Prior to this, loops were of the transformer variety, with the signal being coupled to the receiver via a link turn, wound amongst, but not attached to the windings of the main tank coil. This process did not take into full account transformer theory, as the loop is now a transformer due to the link coupling. The main drawback of the early designs is that they did not use the coefficient of coupling when designing the loops. Moving the winding away, somewhat from the main winding allows for less loading. Maximum energy transfer from the tank to the link would occur at "critical coupling". The load impedance also affects the loading, and should be matched to the impedance of the link turn, as well. As stated before the link should be balanced. A balun, and matching transformer should be used with a modern receiver with a 50 ohm coaxial input. The distance that the link turn is from the primary tank coil greatly affects the performance of the loop. The "Q" can be greatly improved, as well as the S/N ratio if the link turn is placed at the critical coupling point from the main primary tank winding. This distance from the main winding can be approximately determined prior to winding the link turn using a pocket radio. Tune the pocket radio into a station that is within the tuning range of the loop. Start out with the pocket radio placed facing the plane of the loop (see fig 2) right against the loop winding, rotate the loop capacitor for a peak (maximum signal) on the pocket radio. Now move the pocket radio ½" from the winding and re-peak the loop. Observe how sharply that the loop tunes. Move the pocket radio away from the loop in ½" increments. Observe how sharply the loop peaks on the pocket radio, as well as the signal strength at each point. The loop should peak more sharply, and increase its gain as the radio is moved away. The point of critical coupling is attained when the signal is at maximum, the sharpness may still increase somewhat, but the gain will fall off more rapidly as the radio is moved away. Note the critical coupling point, and wind the link coil this distance from the main winding. This process can also be used when passively coupling the loop to a radio using a ferrite antenna, or when using a device such as a Select-A-Tenna, or a shotgun loop , or "Q" stick with a radio with a built in loop.

Mechanical Integrity

Another consideration when building a loop is the mechanical design. This is often overlooked, and can affect the loop balance if the mechanics are sloppy. There are two different types of loop coil designs, The solenoid or box wound, and the spiral or pancake wound. Each type has several advantages, design trade offs, and dis-advantages. The box loop has a higher gain for the same diameter, but is more difficult to balance. With this type of loop there is a trade off between the inter-electrode capacitance and the length to diameter ratio. Spreaders can be used to cut down on the inter-electrode capacitance, and to maintain coil rigidity. Note that the better the length to diameter ratio of the tank coil, the nulling ability is enhanced and balancing is easier. The spiral loop has

the advantage of almost perfect length to diameter ratio, as well as being easier to balance. The main drawback of the spiral is its lower gain than the box loop. Also, if an amplifier is used, it is much more difficult to tap the tank coil at its center. An amplifier can be used more practically with the spiral by attaching it following the balun and matching transformer. This way the amplifier is isolated from the loop, and the undesirable unbalancing effects can be avoided. Note that an amplifier should be used only when necessary, and should be as low in gain as to improve signal strength on very weak signals, where not using it would yield them unreadable. It is important that the loop antenna be well constructed mechanically to insure that the wires do not flop around, to distort the balance, as well as to prohibit the need for re-winding. We have switched from wood to PVC in our designs, with a minimum of metallic objects near the tank, and link coils. Note that metallic objects within the near pick up field of the loop will induce a voltage into the coil unevenly and throw it out of balance.

I have done some portable designs:

- using some slats from a discarded blind set to make a three foot loop
- making a folding loop from some discarded shelves
- a five foot loop using umbrella-like structure.

All collapse into a really compact structure for travel, set up easily. I would say the folding loops is the most cumbersome, the one from blinds is really delicate but fair stable when deployed, the umbrella one really intensive on assembly.
